## High-Efficiency, 40V Step-Up Converters for 2 to 10 White LEDs

$\qquad$ General Description
The MAX1553/MAX1554 drive white LEDs in series with a constant current to provide efficient display backlighting in cellular phones, PDAs, and other hand-held devices. The step-up converter includes an internal 40V, low RDSON, N-channel MOSFET switch for high efficiency and maximum battery life. The MAX1553 has a current limit of 480 mA for driving two to six white LEDs, while the MAX1554 has a current limit of 970 mA for driving up to 10 white LEDs.
A single analog/PWM Dual Mode ${ }^{\text {TM }}$ input provides two simple means of brightness adjustment. A separate enable input provides on/off control. Soft-start minimizes inrush current during startup.
The MAX1553/MAX1554 are available in space-saving 8 -pin TDFN 3mm x 3mm packages.

Applications
Cellular Phones
PDA, Palmtop, and Wireless Handhelds
Color Display Backlight

Dual Mode is a trademark of Maxim Integrated Products, Inc.
Typical Operating Circuit

Features

- Constant-Current Regulation for Even LED Illumination
- Internal 40V MOSFET Switch Capable of Driving 10 LEDs
- Small, Low-Profile External Components
- 2.7V to 5.5V Input Range
- Up to 88\% Efficiency Driving 6 LEDs
- Up to 82\% Efficiency Driving 9 LEDs (20mA, Vcc = 3.6V)
- Analog or PWM Control of LED Intensity
- Optimized for Low Input Ripple
- Soft-Start to Minimize Inrush Current
- $3 \mathrm{~mm} \times 3 \mathrm{~mm}$ 8-Pin TDFN Package

| PIN | NAME | FUNCTION |
| :---: | :---: | :--- |
| 1 | GND | Ground |
| 2 | VCC | Voltage-Supply Input. 2.7V to 5.5V. The IC is powered from VCC. |
| 3 | EN | Enable Input. Drive high or connect to VCC to enable the IC. Drive EN low for shutdown. |
| 4 | BRT | Brightness-Control Input. Either an analog or PWM control signal can be used. The LED current can be <br> controlled over a 10 to 1 range. The PWM signal must be between 100Hz and 10kHz, and must have an <br> amplitude greater than 1.72V. |
| 5 | FB | Feedback Input. Connect to the cathode of the LED string and connect a resistor from FB to GND to set the <br> LED current. |
| 6 | SS | Soft-Start Timing-Control Input. Connect a capacitor from SS to GND to control soft-start timing. See the Soft- <br> Start section for information on selecting the soft-start capacitor. SS is pulled to ground with an internal 200 <br> switch when EN is low. |
| 7 | OV | Overvoltage Sense. Connect to a resistor-divider from the anode of the LED string to set the overvoltage <br> threshold. See Figures 1, 2, and 3. |
| 8 | LX | Inductor Connection. Connect to the inductor and diode. LX is high impedance when EN is low. |
| - | EP | Exposed Pad. Connect to GND. |

## Detailed Description

## Control Scheme

The MAX1553/MAX1554 utilize a minimum off-time, cur-rent-limited control scheme. If the voltage at FB drops below the regulation threshold, the internal low-side MOSFET turns on and the inductor current ramps up to the current limit. Once the current-limit comparator trips, the low-side MOSFET turns off for the minimum off-time (250ns). After 250ns, if the voltage at FB is above the regulation threshold, the low-side MOSFET stays off. If the voltage at FB is below the regulation point, the low-side MOSFET turns back on and the cycle repeats. By using a regulation control scheme that is not fixed frequency and that can skip pulses, the MAX1553/MAX1554 operate with very high efficiency.

## Soft-Start

Soft-start is provided on the MAX1553/MAX1554 to minimize inrush current. The soft-start time is set with an external capacitor, C3 (Figures 1, 2, and 3). Use the following equation to solve for C3:

$$
\mathrm{C} 3=\frac{\mathrm{tSS}}{2 \times 10^{5}}
$$

where tSS is the soft-start time. A value of $0.1 \mu \mathrm{~F}$ provides a soft-start time of 20 ms .

## Shutdown

The MAX1553/MAX1554 feature a low-current shutdown feature. When EN is low, the IC turns off, reducing its supply current to approximately $0.1 \mu \mathrm{~A}$. For normal operation, drive EN high or connect to VCC.

## Overvoltage Protection

The MAX1553/MAX1554 have an adjustable overvoltageprotection circuit. When the voltage at OV reaches the overvoltage threshold (1.25V typ), the protection circuitry prevents the internal MOSFET from switching, allowing the output voltage to decay.
The peak output voltage in an overvoltage-protection event is set with a resistor-divider from the output connected to OV (R2 and R3 in Figures 1, 2, and 3). Select a value for R3 ( $10 \mathrm{k} \Omega$ is recommended), then solve for R2 using the following equation:

$$
\mathrm{R} 2=\mathrm{R} 3 \times\left(\frac{\mathrm{V}_{\mathrm{OUT}(\mathrm{PEAK})}}{\mathrm{V}_{\mathrm{OV}}}-1\right)
$$

where Vov is the overvoltage threshold (1.25V typ), and VOUT(PEAK) is the desired peak output voltage.

Figure 2. Circuit with the MAX1553 Driving Nine White LEDs at Up to 15 mA

# High-Efficiency, 40V Step-Up Converters for 2 to 10 White LEDs 

## Adjusting the LED Current

Adjusting the output current changes the brightness of the LEDs. The LED current is set by the voltage at BRT (VBRT) and the sense resistor (R1) at FB. The VBRT range for adjusting output current is 0 to 1.25 V . Over this range, the LED current is found from the following equation:

$$
\mathrm{L}_{\mathrm{LED}}=\frac{\mathrm{V}_{\mathrm{BRT}}+0.17}{6.67 \times \mathrm{R1}}
$$

BRT can be overdriven; however, applying a VBRT greater than 1.72 V does not increase the output current above the level at 1.72 V . See the LED Current vs. BRT Voltage graph in the Typical Operating Characteristics section. To set the maximum LED current, calculate R1 when $V_{B R T}$ is at its maximum, as follows:

$$
R 1=\frac{V_{\mathrm{BRT}}(\mathrm{MAX})+0.17}{6.67 \times \operatorname{lED}(\mathrm{MAX})}
$$

where $\mathrm{V}_{\mathrm{BRT}}(\mathrm{MAX})$ is 1.72 V if BRT is connected to any value greater than 1.72 V , such as Vcc. Otherwise, $V_{B R T}(M A X)$ is the maximum applied BRT control voltage. Power dissipation in R1 is typically less than 5 mW ; therefore, power dissipation in a standard chip resistor is not a concern.

PWM Dimming Control
The BRT input is also used as a digital input allowing LED brightness control with a logic-level PWM signal applied directly to BRT. The frequency range is from 100 Hz to 10 kHz , and the duty cycle range is 0 to $100 \%$. A 0\% duty cycle corresponds to the minimum current, and a $100 \%$ duty cycle corresponds to full current. See the LED Current vs. BRT Duty Cycle graph in the Typical Operating Characteristics section. The BRT resistor and SS capacitor form a lowpass filter, so PWM dimming results in DC current to the LEDs without the need for additional RC filters.

## Capacitor Selection

A $0.47 \mu \mathrm{~F}$ ceramic output capacitor (C2) is recommended for most applications. For circuits driving six or fewer LEDs, use a $4.7 \mu \mathrm{~F}$ ceramic input capacitor (C1). For circuits driving more than six LEDs, use a $10 \mu \mathrm{~F}$ input capacitor (C1). For best stability over a wide temperature range, use capacitors with an X5R, X7R, or better dielectric.

Figure 3. Circuit with the MAX1554 Driving 10 White LEDs

## Inductor Selection

The MAX1553 has a 480mA inductor current limit and can drive up to six LEDs at 20 mA or nine LEDs at 15 mA . Inductor values from $4.7 \mu \mathrm{H}$ to $47 \mu \mathrm{H}$ work satisfactorily. Larger values provide the best efficiency while small inductor values allow the smallest inductor size. A good choice for best efficiency is the TOKO D62 or D62L series at $47 \mu \mathrm{H}$. For smallest size, the Murata LQH32C at $4.7 \mu \mathrm{H}$ works well.
The MAX1554 has a 970mA inductor current limit and can drive up to 10 LEDs at 20 mA . Inductor values from $4.7 \mu \mathrm{H}$ to $22 \mu \mathrm{H}$ work satisfactorily. A good choice for high efficiency and small size when driving 9 or 10 LEDs is the TOKO D62 series at $22 \mu \mathrm{H}$.
When large inductor values are used to optimize efficiency, the MAX1553/MAX1554 operate with continuous inductor current. With large inductor values (typically greater than $10 \mu \mathrm{H}$ ), stability, input, and output ripple are improved by connecting a capacitor in parallel with the LEDs (C4 in Figures 1, 2, and 3).
To prevent saturation, use an inductor with a current rating that matches the device's LX current limit. However, if size is particularly important, it is sometimes acceptable to operate the inductor $10 \%$ into saturation. For best efficiency, the inductor's DC resistance should also be as low as possible.

## Diode Selection

The MAX1553/MAX1554s' high switching frequency demands a high-speed rectification diode (D1) for optimum efficiency. A Schottky diode is recommended due to its fast recovery time and low forward-voltage drop.

# High-Efficiency, 40V Step-Up Converters for 2 to 10 White LEDs

Ensure the diode's average and peak current ratings exceed the average output current and peak inductor current. In addition, the diode's reverse breakdown voltage must exceed VOUT.

## Applications Information

## Low Input-Voltage Applications

The MAX1553/MAX1554 have minimum input voltages of 2.7V (MAX1553) and 3.15V (MAX1554). However, lower battery voltages can still be boosted for LED drive as long as VCC remains within the operating range. Since most systems have a 3.3 V system supply active when the display is active and backlit, that logic supply can be used to supply VCC, while the battery power connects directly to the boost inductor. No battery current is drawn when EN is low (Figure 4).

PC Board Layout Due to fast-switching waveforms and high-current paths, careful PC board layout is required. An evaluation kit (MAX1553EVKIT) is available as an example of a proper layout.

Figure 4. The MAX1553/MAX1554 can drive LEDs from battery voltages that are lower than the device operating voltage range by powering VCC from a logic supply and connecting the boost inductor to the battery.

When laying out a board, minimize trace lengths between the IC and the inductor, diode, input capacitor, output capacitor, and R1. Keep traces short, direct, and wide. Keep noisy traces, such as the LX node trace, away from FB. Place the VCC bypass capacitor (C1) as close to the IC as possible. The ground connections of C1 and C2 should be as close together as possible. Star connect the grounds for R1, R3, C3, and the BRT voltage supply as close to the IC as possible. The traces from VCC to C1, from C2 to the LEDs, and from the LEDs to R1 can be longer if required.

PROCESS: BiCMOS
