

STEPPER MOTOR CONTROLLER / DRIVER

■ GENERAL DESCRIPTION

NJM3517 is a stepper motor controller/driver, which requires minimum of external components and drive currents up to 500mA.

The NJM3517 is suited for applications requiring least-possible RFI. Operating in a bi-level drive mode can increase motor performance; high voltage pulse is applied to the motor winding at the beginning of a step, in order to give a rapid rise of current.

■ FEATURES

- Internal complete driver and phase logic
- Continuous-output current 2 x 350mA
- Half- and full-step mode generation
- LS-TTL-compatible inputs
- Bi-level drive mode for high step rates
- Voltage-doubling drive possibilities
- Half-step position-indication output
- Minimal RFI
- Packages DIP16 / EMP16

■ PIN DESCRIPTION

DIP	EMP-pack.	Symbol	Description
1	1	P _{B2}	Phase output 2, phase B. Open collector output capable of sinking max 500 mA.
2	2	P _{B1}	Phase output 1, phase B. Open collector output capable of sinking max 500 mA.
3	3	GND	Ground and negative supply for both V _{CC} and V _{SS} .
4	4	P _{A1}	Phase output 1, phase A.
5	5	P _{A2}	Phase output 2, phase A.
6	6	DIR	Direction input. Determines in which rotational direction steps will be taken.
7	7	$\overline{\text{STEP}}$	Stepping pulse. One step is generated for each negative edge of the step signal.
8	8	\emptyset_B	Zero current half step position indication output for phase B.
9	9	\emptyset_A	Zero current half step position indication output for phase A.
10	10	$\overline{\text{HSM}}$	Half-step mode. Determines whether the motor will be operated in half or full-step mot. When pulled low, one step pulse will correspond to a half step of the motor.
11	11	INH	A high level on the inhibit input turns all phase output off.
12	12	R _C	Bi-level pulse timing pin. Pulse time is approximately $t_{on} = 0.55 \cdot R_T \cdot C_T$
13	13	L _A	Second level (bi-level) output, phase A.
14	14	L _B	Second level (bi-level) output, Phase B.
15	15	V _{SS}	Second level supply voltage, +10 to +40 V.
16	16	V _{CC}	Logic supply voltage, nominally +5 V.

FUNCTIONAL DESCRIPTION

The circuit, NJM3517, is a high performance motor driver, intended to drive a stepper motor in a unipolar, bi-level way. Bi-level means that during the first time after a phase shift, the voltage across the motor is increased to a second voltage supply, V_{SS} , in order to obtain a more-rapid rise of current, see figure 25.

The current starts to rise toward a value which is many times greater than the rated winding current. This compensates for the loss in drive current and loss of torque due to the back emf of the motor.

After a short time, t_{ON} , set by the monostable, the bi-level output is switched off and the winding current flows from the V_{MM} supply, which is chosen for rated winding current. How long this time must be to give any increase in performance is determined by V_{SS} voltage and motor data, the L/R time-constant.

In a low-voltage system, where high motor performance is needed, it is also possible to double the motor voltage by adding a few external components, see figure 4.

The time the circuit applies the higher voltage to the motor is controlled by a monostable flip-flop and determined by the timing components R_T and C_T .

The circuit can also drive a motor in traditional unipolar way.

An inhibit input (INH) is used to switch off the current completely.

LOGIC INPUTS

All inputs are LS-TTL compatible. If any of the logic inputs are left open, the circuit will accept it as a HIGH level. NJM3517 contains all phase logic necessary to control the motor in a proper way.

STEP — Stepping pulse

One step is generated for each negative edge of the STEP signal. In half-step mode, two pulses will be required to move one full step. Notice the set up time, t_s , of DIR and HSM signals. These signals must be latched during the negative edge of STEP, see timing diagram, figure 6.

Figure 3.
Typical application

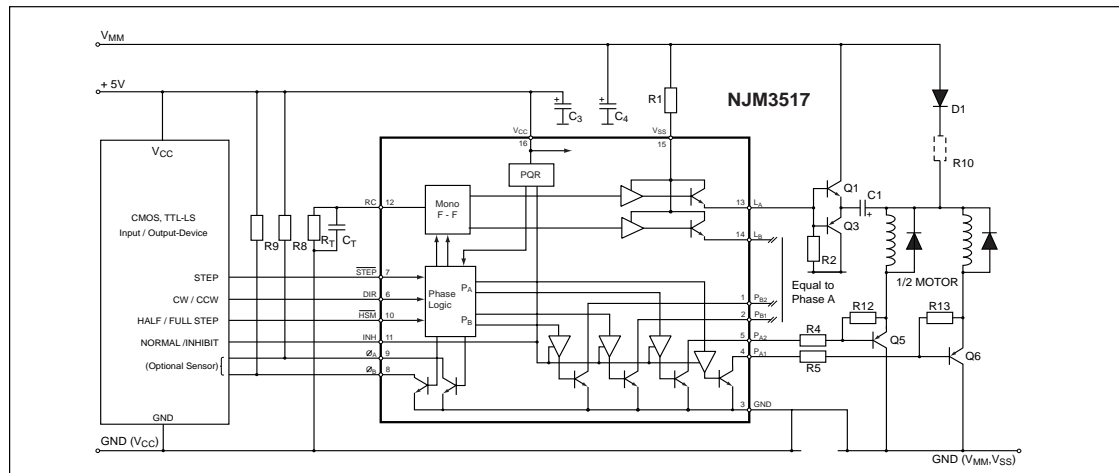

Figure 4.
Voltage doubling with external transistors

DIR — Direction

DIR determines in which direction steps will be taken. Actual direction depends on motor and motor connections. DIR can be changed at any time, but not simultaneously with STEP, see timing diagram, figure 6.

HSM determines whether the motor will be controlled in full-step or half-step mode. When pulled low, a step-pulse will correspond to a half step of the motor. HSM can be changed at any time, but not simultaneously with STEP, see timing diagram, figure 6.

INH — Inhibit

A HIGH level on the INH input, turns off all phase outputs to reduce current consumption.

■ RESET

An internal Power-On Reset circuit connected to V_{cc} resets the phase logic and inhibits the outputs during power up, to prevent false stepping.

■ OUTPUT STAGES

The output stage consists of four open-collector transistors. The second high-voltage supply contains Darlington transistors.

■ PHASE OUTPUT

The phase outputs are connected directly to the motor as shown in figure 3.

■ BI-LEVEL TECHNIQUE

The bi-level pulse generator consists of two monostables with a common RC network.

The internal phase logic generates a trigger pulse every time the phase changes state. The pulse triggers its own monostable which turns on the output transistors for a precise period of time:

$$t_{on} = 0.55 \cdot C_T \cdot R_T$$

See pulse diagrams, figures 7 through 11.

■ BIPOLAR PHASE LOGIC OUTPUT

The \emptyset_A and \emptyset_B outputs are generated from the phase logic and inform an external device if the A phase or the B phase current is internally inhibited. These outputs are intended to support if it is legal to correctly go from a half-step mode to a full-step mode without losing positional information.

The NJM3517 can act as a controller IC for 2 driver ICs, the NJM3770A. Use P_{A1} and P_{B1} for phase control, and \emptyset_A and \emptyset_B for I_0 and I_1 control of current turnoff.

■ ABSOLUTE MAXIMUM RATINGS

Parameter	Pin No.	Symbol	Min	Max	Unit
Voltage					
Logic supply	16	V_{CC}	0	7	V
Second suppl	15	V_{SS}	0	45	V
Logic input	6, 7, 10, 11	V_I	-0.3	6	V
Current					
Phase output	1, 2, 4, 5	I_P	0	500	mA
Second-level output	13, 14	I_L	-500	0	mA
Logic input	6, 7, 10, 11	I_I	-10		mA
The zero output	8, 9	I_O	-	6	mA
Temperature					
Operating junction temperature		T_j	-40	+150	°C
Storage temperature		T_{Stg}	-55	+150	°C
Power Dissipation (Package Data)					
Power dissipation at $T_a = 25^\circ\text{C}$, DIP package. Note 2.		P_D	-	1.6	W
Power dissipation, EMP package. Note 3.		P_D	-	1.3	W

■ RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Min	Typ	Max	Unit
Logic supply voltage	V_{CC}	4.75	5	5.25	V
Second-level supply voltage	V_{SS}	10	-	40	V
Phase output current	I_P	0	-	350	mA
Second-level output current	I_L	-350	-	0	mA
Operating junction temperature	T_J	-20	-	+125	°C
Set up time	t_s	400	-	-	ns
Step pulse duration	t_p	800	-	-	ns

Figure 6. Timing diagram

■ ELECTRICAL CHARACTERISTICS

Electrical characteristics at $T_j = +25^\circ\text{C}$, $V_{CC} = +5.0\text{ V}$, $V_{MM} = +40\text{ V}$, $V_{SS} = +40\text{ V}$ unless otherwise specified.

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Supply current	I_{CC}	INH = LOW	-	45	60	mA
		INH = HIGH	-	12	-	mA
Phase outputs						
Saturation voltage	$V_{PCE\text{ Sat}}$	$I_P = 350\text{ mA}$	-	-	0.85	V
Leakage current	I_{PL}	$V_P = 0\text{ V}$	-	-	500	μA
Turn on, turn off	t_d	+70°C	-	-	3	μs
		+125°C	-	-	6	μs
Second-level outputs						
Saturation voltage	$V_{LCE\text{ Sat}}$	$I_L = -350\text{ mA}$	-	-	2.0	V
Leakage current	I_{LL}	$V_L = 0\text{ V}$	-500	-	-	μA
On time	t_{On}	(note 4)	220	260	300	μs
Logic inputs						
Voltage level, HIGH	V_{IH}		-	2.0	-	V
Voltage level, LOW	V_{IL}		-	-	0.8	V
Input current, LOW	I_{IL}	$V_I = 0.4\text{ V}$	-400	-	-	μA
Input current, HIGH	I_{IH}	$V_I = 2.4\text{ V}$	-	-	20	μA
Logic outputs						
Saturation voltage	$V_{\emptyset CE\text{ Sat}}$	$I_{\emptyset} = 1.6\text{ mA}$	-	-	0.4	V

Notes

1. All voltages are with respect to ground. Current are positive into, negative out of specified terminal.
2. Derates at 12,8 mW/°C above +25°C.
3. Derates at 10.4 mW/°C above +25°C.
4. $R_T = 47\text{ k}\Omega$, $C_T = 10\text{ nF}$.

■ PURPOSE OF EXTERNAL COMPONENTS

For figures 3 and 4. Note that “Larger than ...” is normally the vice versa of “Smaller than ...”

Component	Purpose	Value	Larger than value	Smaller than value
D1, D2	Passes low power to motor and prevents high power from shorting through low power supply	$I_f = 1A$ 1N4001, UF4001	Increases price	Decreases max current capability
D3 ... D6	Inductive current suppressor	$I_f = 1A$	Increases price	Decreases current turn-off capability
		$t_{rr} = 100nS$ e.g. BYV27 UF4001 RGPP10G RGPP30D	Slows down turn-off time. Voltage at anode might exceed voltage breakdown	Speeds up turn-off time.
R1	Base drive current limiter	$R = 20ohm$ $P = R1 \left(\frac{V_{mm}}{R_1 + R_2} \right)^2$	Slows down Q1's turn-on and Q4's turn-off time.	Speeds up Q1's turn-on and Q4's turn-off time.
R2, R3	Base discharge resistor	$R = 240ohm$ $P = R1 \left(\frac{V_{mm}}{R_1 + R_2} \right)^2$	Slows down Q1's turn-off and Q4's turn-on time.	Speeds up Q1's turn-off and Q4's turn-on time.
R4 ... R7	External transistor base driver	$R = \frac{V_{mm} \cdot V_{be} - V_{ce}}{I_4 - \left(\frac{V_{be}}{R_{12}} \right)}$ $P > (I_4)^2 \cdot R_4$ Check hfe.	Decreases ext. transistor I_C max. Lowers 3517 power dissipation.	Increases ext. transistor I_C max. Increases 3517 power dissipation.
R8, R9	$\emptyset A$, $\emptyset B$ pull-up resistors	$R = 5kohm$ @ pull-up voltage = 5V. $P = \frac{(V_{CC})^2}{R}$	Increases noise sensitivity, worse logic-level definition Less stress on $\emptyset A$, $\emptyset B$ output transistors	Increases noise immunity, better logic-level definition. Stress on $\emptyset A$, $\emptyset B$ output transistors.
R10, R11	Limit max. motor current. Resistors may be omitted. (Check motor specifications first.)	$R = \frac{V_{mm} - V_{Motor} - V_{CESat}}{I_{Motor\ max}}$	Decreases motor current.	Increases motor current.
R12 ... R15	External transistor base discharge.	$R = \frac{V_{be}}{I_{12}} = 15\ \Omega$ $P > V_{be} \cdot I_{12}$	Slows down external transistor turn-off time. Lowers 3517 power dissipation	Speeds up external transistor turn-off time. Increases 3517 power dissipation
RT, CT	Sets L_A and L_B on time when triggered by STEP.	$R = 47kohm$, $C = 10nf$ $P < 250mW$	Increases on time.	Decreases on time.
C1, C2	Stores the doubling voltage.	$C = 100\ \mu F$ $V_C \geq 45V$	Increases effective on-time during voltage doubling	Decreases effective on-time during voltage doubling.
C3 ... C5	Filtering of supply-voltage ripple and take-up of energy feedback from D3 ... D6	$C \geq 10\ \mu F$	Increases price, better filtering, decreases risk of IC breakdown	Decreases price, more compact solution.
		$V_{Rated} > V_{mm} \cdot V_{SS}$ or V_{CC}	Increases price	Risk for capacitor breakdown.
Q1, Q2	Activation transistor of voltage doubling.	I_C as motor requires.	Increases price.	Decreases max I_m during voltage doubling.
Q3, Q4	Charging of voltage doubling capacitor	$I_C = \frac{(V_{mm} - V_f - V_{CE}) \cdot C_1}{\left(\frac{1}{f_{Step}} - 0.55 \cdot R_T \cdot C_T \right)}$		
Q5 ... Q8	Motor current drive transistor.	I_C as motor requires. PNP power trans.	Increases max current capability.	Decreases max current capability.

■ APPLICATIONS INFORMATION

Logic inputs

If any of the logic inputs are left open, the circuit will treat it as a high-level input. Unused inputs should be connected to proper voltage levels in order to get the highest noise immunity.

Phase outputs

Phase outputs use a current-sinking method to drive the windings in a unipolar way. A common resistor in the center tap will limit the maximum motor current.

Fast free-wheeling diodes must be used to protect output transistors from inductive spikes.

Series diodes in V_{MM} supply, prevent V_{SS} voltage from shorting through the V_{MM} power supply. However, these may be omitted if no bi-level is used. The V_{SS} pin must not be connected to a lower voltage than V_{MM} , but can be left unconnected.

Zero outputs

Ø_A and Ø_B , “zero A” and “zero B,” are open-collector outputs, which go high when the corresponding phase output is inhibited by the half-step-mode circuitry. A pull-up resistor should be used and connected to a suitable supply voltage (5 kohms for 5V logic). See “Bipolar phase logic output.”

Interference

To avoid interference problems, a good idea is to route separate ground leads to each power supply, where the only common point is at the NJM3517's GND pin. Decoupling of V_{SS} and V_{MM} will improve performance. A 5 kohm pull-up resistor at logic inputs will improve level definitions, especially when driven by open-collector outputs.

■ INPUT AND OUTPUT SIGNALS FOR DIFFERENT DRIVE MODES

The pulse diagrams, figures 7 through 10, show the necessary input signals and the resulting output signals for each drive mode.

On the left side are the input and output signals, the next column shows the state of each signal at the cursor position marked "C."

STEP is shown with a 50% duty cycle, but can, of course, be with any duty cycle, as long as pulse time (t_p) is within specifications.

P_A and P_B are displayed with low level, showing current sinking.

L_A and L_B are displayed with high level, showing current sourcing.

■ USER HINTS

1. Never disconnect ICs or PC-boards when power is supplied.
2. If second supply is not used, disconnect and leave open V_{SS} , L_A , L_B , and RC. Preferably replace the V_{MM} supply diodes (D1, D2) with a straight connection.
3. Remember that excessive voltages might be generated by the motor, even though clamping diodes are used.
4. **Choice of motor.** Choose a motor that is rated for the current you need to establish desired torque. A high supply voltage will gain better stepping performance. If the motor is not specified for the V_{MM} voltage, a current limiting resistor will be necessary to connect in series with center tap. This changes the L/R time constant.
5. Never use L_A or L_B for continuous output at high currents. L_A and L_B on-time can be altered by changing the RC net. An alternative is to trigger the mono-flip-flop by taking a STEP and then externally pulling the RC pin (12Pin) low (0V) for the desired on-time.
6. Avoid V_{MM} and V_{SS} power supplies with serial diodes (without filter capacitor) and/or common ground with V_{CC} . The common place for ground should be as close as possible to the IC's ground pin (pin 3).

7. To change actual motor rotation direction, exchange motor connections at P_{A1} and P_{A2} (or P_{B1} and P_{B2}).
8. **Half-stepping.** In the half-step mode, the power input to the motor alternates between one or two phase windings. In half-step mode, motor resonances are reduced. In a two-phase motor, the electrical phase shift between the windings is 90 degrees. The torque developed is the vector sum of the two windings energized. Therefore, when only one winding is energized, which is the case in half-step mode for every second step, the torque of the motor is reduced by approximately 30%. This causes a torque ripple.
9. **Ramping.** Every drive system has inertia which must be considered in the drive scheme. The rotor and load inertia plays a big role at higher speeds. Unlike the DC motor, the stepper motor is a synchronous motor and does not change speed due to load variations. Examination of typical stepper motors' torque versus speed curves indicates a sharp torque drop-off for the start-stop without error curve. The reason for this is that the torque requirements increase by the cube of the speed change. As it can be seen, for good motor performance, controlled acceleration and deceleration should be considered.

■ COMMON FAULT CONDITIONS

- V_{MM} supply not connected, or V_{MM} supply not connected through diodes.
- The inhibit input not pulled low or floating. Inhibit is active high.
- A bipolar motor without a center tap is used. Exchange motor for unipolar version. Connect according to figure 3.
- External transistors connected without proper base-current supply resistor.
- Insufficient filtering capacitors used.
- Current restrictions exceeded.
- L_A and L_B used for continuous output at high currents. Use the RC network to set a proper duty cycle according to specifications, see figures 19 through 24.
- A common ground wire is used for all three power supplies. If possible, use separate ground leads for each supply to minimize power interference.

■ DRIVE CIRCUITS

If high performance is to be achieved from a stepper motor, the phase must be energized rapidly when turned on and also de-energize rapidly when turned off. In other words, the phase current must increase/decrease rapidly at phase shift.

■ PHASE TURN-OFF CONSIDERATIONS

When the winding current is turned off the induced high voltage spike will damage the drive circuits if not properly suppressed. Different turn-off circuits are used; e. g. :

Diode turn-off circuit (figure 12)

- Slow current decay
- Energy lost mainly in winding resistance
- Potential cooling problems.

Resistance T O C (figure 13)

- Somewhat faster current decay
- Energy lost mainly in R-Ext
- Potential cooling problems

Zener diode T O C (figure 14)

Relatively high V_z gives:

- Relatively fast current decay
- Energy lost mainly in V_z
- Potential cooling problems

Figure 25. Motor Current I_p

Power return T O C for unipolar drive (figure 15)

Relatively high V_z gives:

- Relatively fast current decay
- Energy returned to power supply
- Only small energy losses
- Winding leakage flux must be considered
- Potential cooling problems

Power return to T O C for bi-level drive (figure 16)

- Very fast current decay
- Energy returned to power supply
- Only small energy losses
- Winding leakage flux must be considered

■ DIAGRAMS

How to use the diagrams:

1. What is the maximum motor current in the application?
 - The ambient temperature sets the maximum allowable power dissipation in the IC, which relates to the motor currents and the duty cycle of the Bi-level function. For NJM3517, without any measures taken to reduce the chip temperature via heatsinks, the power dissipation vs. temperature follows the curve in figure 18.
 - Figures 23 and 24 give the relationship between motor currents and their dissipations. The sum of these power dissipations must never exceed the previously-established value, or life expectancy will be drastically shortened.
 - When no Bi-level or voltage doubling is utilized, the maximum motor current can be found directly in figure 23 .
2. How to choose timing components.
 - Figure 21 shows the relationship between C_T , R_T , and t_{On} . Care must be taken to keep the t_{On} time short, otherwise the current in the winding will rise to a value many times the rated current, causing an overheated IC or motor.
3. What is the maximum t_{On} pulse-width at a given frequency?
 - Figure 22 shows the relationship between duty cycle, pulse width, and step frequency. Check specifications for the valid operating area.
4. Figures 17, 18 and 20 show typical saturation voltages vs. output current levels for different output transistors.
5. Shaded areas represent operating conditions outside the safe operating area.
