

FEATURES

6.0 V to 15 V supply range
Supply current: 15 μ A maximum
Low noise: 15 μ V p-p typical (0.1 Hz to 10 Hz)
High output current: 5 mA
Temperature range: -40°C to $+125^{\circ}\text{C}$
Pin-compatible with the REF02/REF19x

APPLICATIONS

Portable instrumentation
Precision reference for 5 V systems
ADC and DAC reference
Solar-powered applications
Loop-current powered instruments

GENERAL DESCRIPTION

The ADR293 is a low noise, micropower precision voltage reference that utilizes an XFET® (eXtra implanted junction FET) reference circuit. The XFET architecture offers significant performance improvements over traditional band gap and buried Zener-based references. Improvements include one quarter the voltage noise output of band gap references operating at the same current, very low and ultralinear temperature drift, low thermal hysteresis, and excellent long-term stability.

The ADR293 is a series voltage reference providing stable and accurate output voltage from a 6.0 V supply. Quiescent current is only 15 μ A maximum, making this device ideal for battery powered instrumentation. Three electrical grades are available offering initial output accuracy of ± 3 mV, ± 6 mV, and ± 10 mV. Temperature coefficients for the three grades are 8 ppm/ $^{\circ}\text{C}$,

15 ppm/ $^{\circ}\text{C}$, and 25 ppm/ $^{\circ}\text{C}$ maximum. Line regulation and load regulation are typically 30 ppm/V and 30 ppm/mA, respectively, maintaining the reference's overall high performance.

The ADR293 is specified over the extended industrial temperature range of -40°C to $+125^{\circ}\text{C}$. This device is available in the 8-lead SOIC and 8-lead TSSOP packages.

ABSOLUTE MAXIMUM RATINGS

Table 5.

Parameter	Rating
Supply Voltage	18 V
Output Short-Circuit Duration to GND	Indefinite
Storage Temperature Range	–65°C to +150°C
Operating Temperature Range	–40°C to +125°C
Junction Temperature Range	–65°C to +150°C
Lead Temperature (Soldering, 60 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} is specified for worst-case conditions; that is, θ_{JA} is specified for the device in socket testing. In practice, θ_{JA} is specified for the device soldered in a circuit board.

Table 6. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
8-Lead SOIC_N (R-8)	158	43	°C/W
8-Lead TSSOP (RU-8)	240	43	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

TERMINOLOGY

Line Regulation

The change in output voltage due to a specified change in input voltage. It includes the effects of self-heating. Line regulation is expressed in percent per volt, parts per million per volt, or microvolts per volt change in input voltage.

Load Regulation

The change in output voltage due to a specified change in load current. It includes the effects of self-heating. Load regulation is expressed in microvolts per milliampere, parts per million per milliampere, or ohms of dc output resistance.

Long-Term Stability

Typical shift of output voltage of 25°C on a sample of parts subjected to high temperature operating life test of 1000 hours at 125°C.

$$\Delta V_{OUT} = V_{OUT}(t_0) - V_{OUT}(t_1)$$

$$\Delta V_{OUT} [\text{ppm}] = \frac{V_{OUT}(t_0) - V_{OUT}(t_1)}{V_{OUT}(t_0)} \times 10^6$$

where:

$V_{OUT}(t_0)$ = V_{OUT} at 25°C at time 0.

$V_{OUT}(t_1)$ = V_{OUT} at 25°C after 1000 hours operation at 125°C.

NC = No Connect

There are in fact connections at NC pins, which are reserved for manufacturing purposes. Users should not connect anything at NC pins.

Temperature Coefficient

The change of output voltage over the operating temperature change and normalized by the output voltage at 25°C, expressed in ppm/°C.

$$TCV_{OUT} [\text{ppm}/^\circ\text{C}] = \frac{V_{OUT}(T_2) - V_{OUT}(T_1)}{V_{OUT}(25^\circ\text{C}) \times (T_2 - T_1)} \times 10^6$$

where:

$V_{OUT}(25^\circ\text{C})$ = V_{OUT} at 25°C.

$V_{OUT}(T_1)$ = V_{OUT} at Temperature 1.

$V_{OUT}(T_2)$ = V_{OUT} at Temperature 2.

Thermal Hysteresis

Thermal hysteresis is defined as the change of output voltage after the device is cycled through temperatures from +25°C to -40°C to +85°C and back to +25°C. This is a typical value from a sample of parts put through such a cycle.

$$V_{OUT-HYS} = V_{OUT}(25^\circ\text{C}) - V_{OUT-TC}$$

$$V_{OUT-HYS} [\text{ppm}] = \frac{V_{OUT}(25^\circ\text{C}) - V_{OUT-TC}}{V_{OUT}(25^\circ\text{C})} \times 10^6$$

where:

$V_{OUT}(25^\circ\text{C})$ = V_{OUT} at 25°C.

V_{OUT-TC} = $V_{OUT}(25^\circ\text{C})$ after temperature cycle at +25°C to -40°C to +85°C and back to +25°C.

THEORY OF OPERATION

The ADR293 uses a new reference generation technique known as XFET, which yields a reference with low noise, low supply current, and very low thermal hysteresis.

The core of the XFET reference consists of two junction field effect transistors, one of which has an extra channel implant to raise its pinch-off voltage. By running the two JFETs at the same drain current, the difference in pinch-off voltage can be amplified and used to form a highly stable voltage reference. The intrinsic reference voltage is around 0.5 V with a negative temperature coefficient of about -120 ppm/K. This slope is essentially locked to the dielectric constant of silicon and can be closely compensated by adding a correction term generated in the same fashion as the proportional-to-temperature (PTAT) term used to compensate band gap references. The big advantage over a band gap reference is that the intrinsic temperature coefficient is some 30 times lower (therefore, less correction is needed) and this results in much lower noise, because most of the noise of a band gap reference comes from the temperature compensation circuitry.

The simplified schematic in Figure 21 shows the basic topology of the ADR293. The temperature correction term is provided by a current source with value designed to be proportional to absolute temperature. The general equation is

$$V_{OUT} = \Delta V_P \left(\frac{R1 + R2 + R3}{R1} \right) + (I_{PTAT})(R3)$$

where:

ΔV_P is the difference in pinch-off voltage between the two FETs.

I_{PTAT} is the positive temperature coefficient correction current.

The process used for the XFET reference also features vertical NPN and PNP transistors, the latter of which are used as output devices to provide a very low dropout voltage.

Figure 21. Simplified Schematic

DEVICE POWER DISSIPATION CONSIDERATIONS

The ADR293 is guaranteed to deliver load currents to 5 mA with an input voltage that ranges from 5.5 V to 15 V. When this device is used in applications with large input voltages, care should be exercised to avoid exceeding the published specifications for maximum power dissipation or junction temperature that could result in premature device failure. The following formula should be used to calculate a device's maximum junction temperature or dissipation:

$$P_D = \frac{T_J - T_A}{\theta_{JA}}$$

where:

T_J and T_A are the junction temperature and ambient temperature, respectively.

P_D is the device power dissipation.

θ_{JA} is the device package thermal resistance.

BASIC VOLTAGE REFERENCE CONNECTIONS

References, in general, require a bypass capacitor connected from the V_{OUT} pin to the GND pin. The circuit in Figure 22 illustrates the basic configuration for the ADR293. Note that the decoupling capacitors are not required for circuit stability.

Figure 22. Basic Voltage Reference Configuration

NOISE PERFORMANCE

The noise generated by the ADR293 is typically less than 15 μ V p-p over the 0.1 Hz to 10 Hz band. The noise measurement is made with a band-pass filter made of a 2-pole high-pass filter with a corner frequency at 0.1 Hz and a 2-pole low-pass filter with a corner frequency at 10 Hz.

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are the time for the active circuits to settle and the time for the thermal gradients on the chip to stabilize. Figure 15 shows the typical turn-on time for the ADR293.

APPLICATIONS

A NEGATIVE PRECISION REFERENCE WITHOUT PRECISION RESISTORS

In many current-output CMOS DAC applications where the output signal voltage must be of the same polarity as the reference voltage, it is often required to reconfigure a current-switching DAC into a voltage-switching DAC by using a 1.25 V reference, an op amp, and a pair of resistors. Using a current-switching DAC directly requires the need for an additional operational amplifier at the output to reinvert the signal. Therefore, a negative voltage reference is desirable from the point that an additional operational amplifier is not required for either reinversion (current-switching mode) or amplification (voltage-switching mode) of the DAC output voltage. In general, any positive voltage reference can be converted into a negative voltage reference by using an operational amplifier and a pair of matched resistors in an inverting configuration. The disadvantage to that approach is that the largest single source of error in the circuit is the relative matching of the resistors used.

The circuit illustrated in Figure 23 avoids the need for tightly matched resistors with the use of an active integrator circuit. In this circuit, the output of the voltage reference provides the input drive for the integrator. To maintain circuit equilibrium, the integrator adjusts its output to establish the proper relationship between the reference's V_{OUT} and GND. One caveat with this approach should be mentioned. Although rail-to-rail output amplifiers work best in the application, these operational amplifiers require a finite amount (mV) of headroom when required to provide any load current. The choice for the circuit's negative supply should take this issue into account.

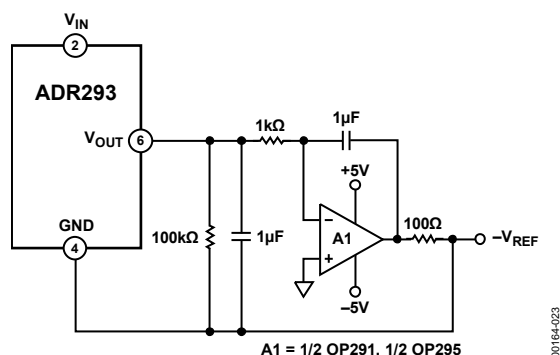

Figure 23. A Negative Precision Voltage Reference Uses No Precision Resistors

A PRECISION CURRENT SOURCE

Many times in low power applications, the need arises for a precision current source that can operate on low supply voltages. As shown in Figure 24, the ADR293 is configured as a precision current source. The circuit configuration illustrated is a floating current source with a grounded load. The output

voltage of the reference is bootstrapped across R_{SET} , which sets the output current into the load. With this configuration, circuit precision is maintained for load currents in the range from the reference's supply current, typically 15 μ A to approximately 5 mA.

Figure 24. A Precision Current Source

KELVIN CONNECTIONS

In many portable instrumentation applications where PC board cost and area go hand-in-hand, circuit interconnects are very often of dimensionally minimum width. These narrow lines can cause large voltage drops if the voltage reference is required to provide load currents to various functions. In fact, a circuit's interconnects can exhibit a typical line resistance of 0.45 m Ω /square (1 oz. Cu, for example). Force and sense connections, also referred to as Kelvin connections, offer a convenient method of eliminating the effects of voltage drops in circuit wires. Load currents flowing through wiring resistance produce an error ($V_{ERROR} = R \times I_L$) at the load. However, the Kelvin connection in Figure 25 overcomes the problem by including the wiring resistance within the forcing loop of the op amp. Because the op amp senses the load voltage, op amp loop control forces the output to compensate for the wiring error and to produce the correct voltage at the load.

Figure 25. Advantage of Kelvin Connection

ADR293

VOLTAGE REGULATOR FOR PORTABLE EQUIPMENT

The ADR293 is ideal for providing a stable, low cost, and low power reference voltage in portable equipment power supplies. Figure 26 shows how the ADR293 can be used in a voltage regulator that not only has low output noise (as compared to switch mode design) and low power, but also a very fast recovery after current surges. Some precautions should be taken in the selection of the output capacitors. Too high an ESR (effective series resistance) could endanger the stability of the circuit. A solid tantalum capacitor, 16 V or higher, and an aluminum electrolytic capacitor, 10 V or higher, are recommended for C1 and C2, respectively. In addition, the path from the ground side of C1 and C2 to the ground side of R1 should be kept as short as possible.
