EVALUATION KIT AVAILABLE High-Efficiency, Step-Up DC-DC Converter

General Description

The MAX1678 is a high-efficiency, low-voltage, synchronous-rectified, step-up DC-DC converter intended for use in devices powered by 1 to 3-cell alkaline, NiMH, or NiCd batteries or a 1-cell lithium battery. It guarantees a 0.87V start-up voltage and features a low 37μ A quiescent supply current.

The device includes a 1 Ω , N-channel MOSFET power switch, a synchronous rectifier that acts as the catch diode, a reference, pulse-frequency-modulation (PFM) control circuitry, and circuitry to reduce inductor ringing—all in an ultra-small, 1.1mm-high µMAX package.

The output voltage is preset to 3.3V or can be adjusted from +2V to +5.5V using only two resistors. Efficiencies up to 90% are achieved for loads up to 50mA. The device also features an independent undervoltage comparator (PFI/PFO) and a logic-controlled 2µA shutdown mode.

_Features

- 0.87V Guaranteed Start-Up
- Up to 90% Efficiency
- + Built-In Synchronous Rectifier (no external diode)
- Ultra-Small µMAX Package, 1.1mm High
- 37µA Quiescent Current (85µA from 1.5V battery)
- ♦ 2µA Logic-Controlled Shutdown
- Power-Fail Detector
- Dual Mode[™] Output: Fixed 3.3V Adjustable 2V to 5.5V
- 45mA Output Current at 3.3V for 1-Cell Input
- + 90mA Output Current at 3.3V for 2-Cell Input
- Inductor-Damping Switch Suppresses EMI

Note 1: The reverse battery current is measured from the *Typical Operating Circuit's* input terminal to GND when the battery is connected backward. A reverse current of 220mA will not exceed package dissipation limits but, if left for an extended time (more than 10 minutes), may degrade performance.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Detailed Description

The MAX1678 consists of an internal 1 Ω , N-channel MOSFET power switch, a built-in synchronous rectifier that acts as the catch diode, a reference, PFM control circuitry, and an inductor damping switch (Figure 1).

The device is optimized for applications that are powered by 1 to 3-cell alkaline, NiMH, or NiCd batteries, or a 1-cell lithium battery such as pagers, remote controls, and battery-powered instruments. They are designed to meet the specific demands of the operating states characteristic of such systems:

 Primary battery is good and load is active: In this state the load draws tens of milliamperes and the MAX1678 typically offers 80% to 90% efficiency.

- 2) *Primary battery is good and load is sleeping:* In this state the load draws hundreds of microamperes and the DC-DC converter IC draws very low quiescent current. Many applications maintain the load in this state most of the time.
- 3) *Primary battery is dead and DC-DC converter is shut down:* In this state the load is sleeping or supplied by the backup battery, and the MAX1678 draws 0.1µA current from the OUT pin.
- 4) *Primary and backup battery dead:* The DC-DC converter can restart from this condition.

7

Operating Principle

The MAX1678 employs a proprietary constant-peakcurrent control scheme that combines the ultra-low quiescent current of traditional pulse-skipping PFM converters with high-load efficiency.

When the error comparator detects that the output voltage is too low, it turns on the internal N-channel MOSFET switch for an internally calculated on-time (Figure 2). During the on-time, current ramps up in the inductor, storing energy in the magnetic field. When the MOSFET turns off during the second half of each cycle, the magnetic field collapses, causing the inductor voltage to force current through the synchronous rectifier, transferring the stored energy to the output filter capacitor and the load. The output filter capacitor stores charge while the current from the inductor is high, then holds up the output voltage until the second half of the next switching cycle, smoothing power flow to the load. The ideal on-time of the N-channel MOSFET changes as a function of input voltage. The on-time is determined as follows:

$$t_{ON} = \frac{K}{V_{BATT}}$$

where K is typically 8V-µs.

The peak inductor current (assuming a lossless circuit) can be calculated from the following equation:

$$I_{\text{PEAK}} = \frac{k}{L}$$

The P-channel MOSFET (synchronous rectifier) turns on when the N-channel MOSFET turns off. The circuit operates at the edge of discontinuous conduction; therefore, the P-channel synchronous rectifier turns off immediately after the inductor current ramps to zero. During the dead time after the P-switch has been turned off, the damping switch connects LX and BATT. This suppresses EMI noise due to LC ringing of the inductor and parasitic capacitance at the LX node (see *Damping Switch* section). The error comparator starts another cycle when VouT falls below the regulation threshold. With this control scheme, the MAX1678 maintains high efficiency over a wide range of loads and input/output voltages while minimizing switching noise.

Start-Up Operation

The MAX1678 contains a low-voltage start-up oscillator (Figure 1). This oscillator pumps up the output voltage to approximately 1.7V, the level at which the main DC-DC converter can operate. The 150kHz fixed-frequency oscillator is powered from the BATT input and drives an NPN switch. During start-up, the P-channel synchronous

Figure 2. Switching Waveforms

Figure 3. External Schottky Diode to Improve Start-Up with Heavy Load

rectifier remains off and its body diode (or an external diode, if desired) is used as an output rectifier. The minimum start-up voltage is a function of load current (see *Typical Operating Characteristics*). In normal operation, when the voltage at the OUT pin exceeds 1.7V, the DC-DC converter is powered from the OUT pin (bootstrapped) and the main control circuitry is enabled.

Once started, the output can maintain the load as the battery voltage decreases below the start-up voltage. To improve start-up capability with heavy loads, add a Schottky diode in parallel with the P-channel synchronous rectifier (from LX to OUT) as shown in Figure 3 (see *Typical Operating Characteristics*).

Shutdown Mode

Pulling the SHDN pin low places the MAX1678 in shutdown mode (I_{SHDN} = 2μ A typical). In shutdown, the internal switching MOSFET turns off, PFO goes high impedance, and the synchronous rectifier turns off to prevent the flow of reverse current from the output back to the input. However, there is still a forward current path through the synchronous-rectifier body diode from the input to the output. Thus, in shutdown, the output remains one diode drop below the battery voltage (VBATT).

To disable the shutdown feature, connect $\overline{\text{SHDN}}$ (a logic input) to BATT or OUT.

Reverse-Battery Protection

The MAX1678 can sustain/survive battery reversal up to the package power-dissipation limit. An internal 5 Ω resistor in series with a diode limits reverse current to less than 220mA, preventing damage. Prolonged operation above 220mA reverse-battery current can degrade the device's performance.

Power-Fail Comparator

The MAX1678 has an on-chip comparator for power-fail detection. This comparator can detect a loss of power at the input or output (Figures 7 and 8). If the voltage at the power-fail input (PFI) falls below 614mV, the PFO output sinks current to GND. Hysteresis at PFI is 2%. The power-fail monitor threshold is set by two resistors, R3 and R4, using the following equation:

$$R3 = R4 \times \left(\frac{V_{TH}}{V_{PFI}} - 1\right)$$

where V_{TH} is the desired threshold of the power-fail detector, and V_{PFI} is the 614mV threshold of the power-fail comparator. Since PFI leakage is 10nA max, select feedback resistor R4 in the 100k Ω to 1M Ω range.

Damping Switch

The MAX1678 is designed with an internal damping switch to minimize ringing at the LX node. The damping switch (Figure 4) connects the LX node to BATT, effectively depleting the inductor's remaining energy. When the energy in the inductor is insufficient to supply current to the output, the capacitance and inductance at LX form a resonant circuit that causes ringing. The damping switch supplies a path to quickly dissipate this energy, suppressing the ringing at LX. This does not reduce the output ripple, but does reduce EMI. Figures 5 and 6 show the LX node voltage waveform without and with the damping switch.

Figure 4. Simplified Diagram of Damping Switch

Applications Information

Output Voltage Selection

The MAX1678 operates with a fixed 3.3V or adjustable output. To select fixed-voltage operation, connect FB to GND (Figure 7). For an adjustable output between 2V and 5.5V, connect FB to a resistor voltage-divider between OUT and GND (Figure 8). FB regulates to 1.23V.

Since FB leakage is 10nA max, select feedback resistor R2 in the $100k\Omega$ to $1M\Omega$ range. R1 is given by:

$$R1 = R2 x \left(\frac{V_{OUT}}{V_{REF}} - 1 \right)$$

where $V_{REF} = 1.23V$.

Maximum Output Current and Inductor Selection

The MAX1678 is designed to work well with a 47μ H inductor in most low-power applications. 47μ H is a sufficiently low value to allow the use of a small surfacemount coil, but large enough to maintain low ripple. The *Typical Operating Characteristics* section shows performance curves with several 47μ H and 22μ H coils. Low inductance values supply higher output current but also increase ripple and reduce efficiency. Note that values below 22μ H are not recommended due to MAX1678 switch limitations. Higher inductor values reduce peak inductor current (and consequent ripple and noise) and improve efficiency, but also limit output current.

The relationship between current and inductor value is approximately:

10

$$I_{OUT(MAX)} = M \times \frac{1}{2} \times \frac{K}{L} \times \frac{V_{BATT}}{V_{OUT}}$$

where M is an empirical factor that takes into account losses in the MAX1678 internal switches and in the inductor resistance. K is the V- μ s factor that governs the inductor charge time. Nominally, M = 0.9 and K = 8V- μ s. M should be further reduced by 0.1 for each ohm of inductor resistance.

The inductor's saturation-current rating must exceed the worst-case peak current limit set by the MAX1678's timing algorithm:

$$I_{PEAK} = \frac{K_{MAX}}{L}$$

where $K_{MAX} = 11.2V$ -µs. It is usually acceptable to exceed most coil saturation-current ratings by 20% with no ill effects; however, the maximum recommended IPEAK for the MAX1678 internal switches is 550mA, so inductor values below 22µH are not recommended. For optimum efficiency, inductor series resistance should be less than 150mV/IPEAK. Table 1 lists suggested inductors and suppliers.

Capacitor Selection

Choose input and output capacitors to service input and output peak currents with acceptable voltage ripple. Capacitor ESR is a major contributor to output ripple (usually more than 60%). A 10μ F, ceramic output filter capacitor typically provides 50mV output ripple when stepping up from 1.3V to 3.3V at 20mA. Low input to output voltage differences (i.e., 2 cells to 3.3V) require higher capacitor values (10μ F to 47μ F).

The input filter capacitor (C_{IN}) also reduces peak currents drawn from the battery and improves efficiency. Low-ESR capacitors are recommended. Ceramic capacitors have the lowest ESR, but low-ESR tantalums represent a good balance between cost and performance. Low-ESR aluminum electrolytic capacitors are tolerable, and standard aluminum electrolytic capacitors should be avoided. Capacitance and ESR variation over temperature need to be taken into consideration for best performance in applications with wide operating temperature ranges. Table 2 lists suggested capacitors and suppliers.

Minimizing Noise and Voltage Ripple

EMI and output voltage ripple can be minimized by following these simple design rules:

- Place the DC-DC converter and digital circuitry on the opposite corner of the PC board from sensitive RF and analog input stages.
- 2) Use a closed-core inductor, such as toroid or shielded bobbin, to minimize fringe magnetic fields.
- Choose the largest inductor value that satisfies the load requirement, to minimize peak switching current and the resulting ripple and noise.
- 4) Use low-ESR input and output filter capacitors.

5) Follow sound circuit-board layout and grounding rules (see the *PC Board Layout and Grounding* section).

PC Board Layout and Grounding

High switching frequencies and large peak currents make PC board layout an important part of design. Poor design can result in excessive EMI on the feedback paths and voltage gradients in the ground plane. Both of these factors can result in instability or regulation errors. The OUT pin must be bypassed directly to GND, as close to the IC as possible (within 0.2 inches or 5mm).

Place power components—such as the MAX1678, inductor, input filter capacitor, and output filter capacitor—as close together as possible. Keep their traces short, direct, and wide (≥50 mil or 1.25mm), and place their ground pins close together in a star-ground configuration. Keep the extra copper on the board and integrate it into ground as a pseudo-ground plane. On multilayer boards, route the star ground using component-side copper fill, then connect it to the internal ground plane using vias.

Place the external voltage-feedback network very close to the FB pin (within 0.2 inches or 5mm). Noisy traces, such as from the LX pin, should be kept away from the voltage-feedback network and separated from it using grounded copper. The MAX1678 evaluation kit manual shows an example PC board layout, which includes a pseudo-ground plane.
