### **General Description**

Applications

The MAX5080/MAX5081 are 250kHz PWM step-down DC-DC converters with an on-chip,  $0.3\Omega$  high-side switch. The input voltage range is 4.5V to 40V for the MAX5080 and 7.5V to 40V for the MAX5081. The output is adjustable from 1.23V to 32V and can deliver up to 1A of load current.

Both devices utilize a voltage-mode control scheme for good noise immunity in the high-voltage switching environment and offer external compensation allowing for maximum flexibility with a wide selection of inductor values and capacitor types. The switching frequency is internally fixed at 250kHz and can be synchronized to an external clock signal through the SYNC input. Light load efficiency is improved by automatically switching to a pulse-skip mode.

All devices include programmable undervoltage lockout and soft-start. Protection features include cycle-bycycle current limit, hiccup-mode output short-circuit protection, and thermal shutdown. Both devices are available in a space-saving, high-power (2.7W), 16-pin TQFN package and are rated for operation over the -40°C to +125°C temperature range.

- 4.5V to 40V (MAX5080) or 7.5V to 40V (MAX5081) Input Voltage Range
- A Output Current
- ♦ Vout Range From 1.23V to 32V
- Internal High-Side Switch
- Fixed 250kHz Internal Oscillator
- Automatic Switchover to Pulse-Skip Mode at Light Loads
- External Frequency Synchronization
- Thermal Shutdown and Short-Circuit Protection
- Operates Over the -40°C to +125°C Temperature Range
- Space-Saving (5mm x 5mm) High-Power 16-Pin TQFN Package

### \_Ordering Information

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

| 13, 14  | 13, 14  | IN     | Supply Input Connection. Connect to an external voltage source from 4.5V to 40V (MAX5080) or a 7.5V to 40V (MAX5081).   |
| 15      | 15      | REG    | Internal Regulator Output. 5V output for the MAX5080 and 8V output for the MAX5081. Bypass to SGND with at least a $1\mu$ F ceramic capacitor.  |
| 16      | 16      | SGND   | Signal Ground Connection. Solder the exposed pad to a large SGND plane. Connect SGND and PGND together at one point near the input bypass capacitor return terminal.  |
| EP      | EP      | EP     | Exposed Pad. Connect exposed pad to SGND.   |

### **Detailed Description**

The MAX5080/MAX5081 are voltage-mode buck converters with internal  $0.3\Omega$  power MOSFET switches. The MAX5080 has a wide input voltage range of 4.5V to 40V. The MAX5081's input voltage range is 7.5V to 40V. The internal low RDS\_ON switch allows for up to 1A of output current. The 250kHz fixed switching frequency, external compensation, and voltage feed-forward simplify loop compensation design and allow for a variety of L and C filter components. Both devices offer an

automatic switchover to pulse-skipping (PFM) mode, providing low quiescent current and high efficiency at light loads. Under no load, a PFM mode operation reduces the current consumption to only 1.4mA. In shutdown, the supply current falls to 200µA. Additional features include an externally programmable undervoltage lockout through the ON/OFF pin, a programmable soft-start, cycle-by-cycle current limit, hiccup mode output short-circuit protection, and thermal shutdown.

Figure 1. MAX5080 Simplified Block Diagram

#### **Internal Linear Regulator (REG)**

REG is the output terminal of a 5V (MAX5080), or 8V (MAX5081) LDO which is powered from IN and provides power to the IC. Connect REG externally to DVREG to provide power for the high-side MOSFET gate driver. Bypass REG to SGND with a ceramic capacitor of at least 1 $\mu$ F. Place the capacitor physically close to the MAX5080/MAX5081 to provide good bypassing. During normal operation, REG is intended for powering up only the internal circuitry and should not be used to supply power to external loads.

#### Internal UVLO/External UVLO

The MAX5080/MAX5081 provides two undervoltage lockouts (UVLOs). An internal UVLO looks at the input voltage (V<sub>IN</sub>) and is fixed at 4.1V (MAX5080) or 7.1V (MAX5081). An external UVLO is sensed and programmed at the ON/ $\overline{OFF}$  pin. The external UVLO over-

rides the internal UVLO when the external UVLO is higher than the internal UVLO. During startup, before any operation begins, the input voltage and the voltage at ON/OFF must exceed their respective UVLOs. The external UVLO has a rising threshold of 1.23V with 0.12V of hysteresis. Program the external UVLO by connecting a resistive divider from IN to ON/OFF to SGND. Connect ON/OFF to IN directly to disable the external UVLO.

Driving ON/OFF to ground places the MAX5080/ MAX5081 in shutdown. When in shutdown the internal power MOSFET turns off, all internal circuitry shuts down and the quiescent supply current reduces to 200µA. Connect an RC network from ON/OFF to SGND to set a turn-on delay that can be used to sequence the output voltages of multiple devices.

Figure 2. MAX5081 Simplified Block Diagram

#### **Soft-Start and Reference (SS)**

SS is the 1.23V reference bypass connection for the MAX5080/MAX5081 and also controls the soft-start period. At startup, after V<sub>IN</sub> is applied and the internal and external UVLO thresholds are reached, the device enters soft-start. During soft-start, 15µA is sourced into the capacitor (C<sub>SS</sub>) connected from SS to SGND causing the reference voltage to ramp up slowly. When V<sub>SS</sub> reaches 1.23V the output becomes fully active. Set the soft-start time (t<sub>SS</sub>) using following equation:

$$t_{SS} = \frac{1.23V \times C_{SS}}{15\mu A}$$

where tss is in seconds and Css is in Farads.

#### Internal Charge Pump (MAX5080)

The MAX5080 features an internal charge pump to enhance the turn-on of the internal MOSFET, allowing for operation with input voltages down to 4.5V. Connect a flying capacitor (CF) between C+ and C-, a boost diode from C+ to BST, as well as a bootstrap capacitor (C<sub>BST</sub>) between BST and LX to provide the gate drive voltage for the high-side n-channel DMOS switch. During the on-time, the flying capacitor is charged to V<sub>DVREG</sub>. During the off-time, the positive terminal of the flying capacitor (C+) is pumped to two times V<sub>DVREG</sub> and charge is dumped onto C<sub>BST</sub> to provide twice the regulator voltage across the high-side DMOS driver. Use a ceramic capacitor of at least 0.1µF for C<sub>BST</sub> and CF located as close to the device as possible.

For applications that do not require a 4.5V minimum input, use the MAX5081. In this device the charge pump is omitted and the input voltage range is from 7.5V to 40V. In this situation the boost diode and the boost capacitor are still required (see the *MAX5081 Typical Operating Circuit*).

#### Gate Drive Supply (DVREG)

DVREG is the supply input for the internal high-side MOSFET driver. The power for DVREG is derived from the output of the internal regulator (REG). Connect DVREG to REG externally. We recommend the use of an RC filter (1 $\Omega$  and 0.47 $\mu$ F) from REG to DVREG to filter the noise generated by the switching of the charge pump. In the MAX5080, the high-side drive supply is generated using the internal charge pump along with the bootstrap diode and capacitor. In the MAX5081, the high-side MOSFET driver supply is generated using only the bootstrap diode and capacitor.

**Error Amplifier** The output of the internal error amplifier (COMP) is available for frequency compensation (see the *Compensation Design* section). The inverting input is FB, the noninverting input SS, and the output COMP. The error amplifier has an 80dB open-loop gain and a 1.8MHz GBW product. See the *Typical Operating Character-istics* for the Gain and Phase vs. Frequency graph.

#### **Oscillator/Synchronization Input (SYNC)**

With SYNC tied to SGND, the MAX5080/MAX5081 use their internal oscillator and switch at a fixed frequency of 250kHz. For external synchronization, drive SYNC with an external clock from 150kHz to 350kHz. When driven with an external clock, the device synchronizes to the rising edge of SYNC.

#### **PWM Comparator/Voltage Feedforward**

An internal 250kHz ramp generator is compared against the output of the error amplifier to generate the PWM signal. The maximum amplitude of the ramp (V<sub>RAMP</sub>) automatically adjusts to compensate for input voltage and oscillator frequency changes. This causes the V<sub>IN</sub>/V<sub>RAMP</sub> to be a constant 10V/V across the input voltage range of 4.5V to 40V (MAX5080) or 7.5V to 40V (MAX5081) and the SYNC frequency range of 150kHz to 350kHz.

#### Output Short-Circuit Protection (Hiccup Mode)

The MAX5080/MAX5081 protects against an output short circuit by utilizing hiccup-mode protection. In hiccup mode, a series of sequential cycle-by-cycle current-limit events will cause the part to shut down and restart with

MIXXI/M

a soft-start sequence. This allows the device to operate with a continuous output short circuit.

During normal operation, the current is monitored at the drain of the internal power MOSFET. When the current limit is exceeded, the internal power MOSFET turns off until the next on-cycle and a counter increments. If the counter counts seven consecutive current-limit events, the device discharges the soft-start capacitor and shuts down for 512 clock periods before restarting with a soft-start sequence. Each time the power MOSFET turns on and the device does not exceed the current limit, the counter is reset.

#### **Thermal-Overload Protection**

The MAX5080/MAX5081 feature an integrated thermaloverload protection. Thermal-overload protection limits the total power dissipation in the device and protects it in the event of an extended thermal fault condition. When the die temperature exceeds +160°C, an internal thermal sensor shuts down the part, turning off the power MOSFET and allowing the IC to cool. After the temperature falls by 20°C, the part will restart with a soft-start sequence.

### Applications Information

### Setting the <u>Un</u>dervoltage Lockout

When the voltage at ON/OFF rises above 1.23V, the MAX5080/MAX5081 turns on. Connect a resistive divider from IN to ON/OFF to SGND to set the UVLO threshold (see Figure 5). First select the ON/OFF to the SGND resistor (R2) then calculate the resistor from IN to ON/OFF (R1) using the following equation:

$$R1 = R2 \times \left[\frac{V_{IN}}{V_{ON}/\overline{OFF}} - 1\right]$$

where V\_IN is the input voltage at which the converter turns on, V\_ON/OFF = 1.23V and R2 is chosen to be less than 600k  $\Omega.$ 

If the external UVLO divider is not used, connect ON/OFF to IN directly. In this case, an internal undervoltage lockout feature monitors the supply voltage at IN and allows operation to start when IN rises above 4.1V (MAX5080) and 7.1V (MAX5081).

#### Setting the Output Voltage

Connect a resistive divider from OUT to FB to SGND to set the output voltage. First calculate the resistor from OUT to FB using the guidelines in the *Compensation Design* section. Once R3 is known, calculate R4 using the following equation:

$$R4 = \frac{R3}{\left[\frac{V_{OUT}}{V_{FB}} - 1\right]}$$

where  $V_{FB} = 1.23V$ .

#### **Inductor Selection**

Three key inductor parameters must be specified for operation with the MAX5080/MAX5081: inductance value (L), peak inductor current (IPEAK), and inductor saturation current (ISAT). The minimum required inductance is a function of operating frequency, input-to-output voltage differential, and the peak-to-peak inductor current  $(\Delta I_{P-P})$ . Higher  $\Delta I_{P-P}$  allows for a lower inductor value while a lower  $\Delta I_{P-P}$  requires a higher inductor value. A lower inductor value minimizes size and cost and improves large-signal and transient response, but reduces efficiency due to higher peak currents and higher peak-to-peak output voltage ripple for the same output capacitor. On the other hand, higher inductance increases efficiency by reducing the ripple current. Resistive losses due to extra wire turns can exceed the benefit gained from lower ripple current levels especially when the inductance is increased without also allowing for larger inductor dimensions. A good compromise is to choose  $\Delta I_{P-P}$  equal to 40% of the full load current. Calculate the inductor using the following equation:

$$L = \frac{V_{OUT}(V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times \Delta I_{P-P}}$$

V<sub>IN</sub> and V<sub>OUT</sub> are typical values so that efficiency is optimum for typical conditions. The switching frequency (fsw) is fixed at 250kHz or can vary between 150kHz and 350kHz when synchronized to an external clock (see the *Oscillator/Synchronization Input (SYNC)* section). The peak-to-peak inductor current, which reflects the peak-topeak output ripple, is worst at the maximum input voltage. See the *Output Capacitor Selection* section to verify that the worst-case output ripple is acceptable. The inductor saturating current (ISAT) is also important to avoid runaway current during continuous output short circuit. Select an inductor with an ISAT specification higher than the maximum peak current limit of 2.6A.

#### Input Capacitor Selection

The discontinuous input current of the buck converter causes large input ripple currents and therefore the input capacitor must be carefully chosen to keep the input voltage ripple within design requirements. The input voltage ripple is comprised of  $\Delta V_Q$  (caused by the capacitor discharge) and  $\Delta V_{ESR}$  (caused by the ESR of

the input capacitor). The total voltage ripple is the sum of  $\Delta V_Q$  and  $\Delta V_{ESR}$ . Calculate the input capacitance and ESR required for a specified ripple using the following equations:

$$ESR = \frac{\Delta V_{ESR}}{\left(I_{OUT\_MAX} + \frac{\Delta I_{P-P}}{2}\right)}$$
$$C_{IN} = \frac{I_{OUT\_MAX} \times D(1-D)}{\Delta V_{Q} \times f_{SW}}$$

where

$$\Delta I_{P\text{-}P} = \frac{(V_{IN} - V_{OUT}) \times V_{OUT}}{V_{IN} \times f_{SW} \times L} \text{ and}$$

$$D = \frac{V_{OUT}}{V_{IN}}$$

 $I_{OUT\_MAX}$  is the maximum output current, D is the duty cycle, and  $f_{SW}$  is the switching frequency.

The MAX5080/MAX5081 includes internal and external UVLO hysteresis and soft-start to avoid possible unintentional chattering during turn-on. However, use a bulk capacitor if the input source impedance is high. Use enough input capacitance at lower input voltages to avoid possible undershoot below the undervoltage lockout threshold during transient loading.

#### **Output Capacitor Selection**

The allowable output voltage ripple and the maximum deviation of the output voltage during load steps determine the output capacitance and its ESR. The output ripple is mainly composed of  $\Delta V_Q$  (caused by the capacitor discharge) and  $\Delta V_{ESR}$  (caused by the voltage drop across the equivalent series resistance of the output capacitor). The equations for calculating the peak-to-peak output voltage ripple are:

$$\Delta V_{Q} = \frac{\Delta I_{PP}}{16 \times C_{OUT} \times f_{SW}}$$

$$\Delta V_{ESR} = ESR \times \Delta I_{P-P}$$

Normally, a good approximation of the output voltage ripple is  $\Delta V_{\text{RIPPLE}} \approx \Delta V_{\text{ESR}} + \Delta V_{\text{Q}}$ . If using ceramic capacitors, assume the contribution to the output voltage ripple from ESR and the capacitor discharge to be

## Downloaded from Elcodis.com electronic components distributor

## 1A, 40V, MAXPower Step-Down DC-DC Converters

equal to 20% and 80%, respectively.  $\Delta I_{P-P}$  is the peak-topeak inductor current (see the *Input Capacitors Selection* section) and f<sub>SW</sub> is the converter's switching frequency.

The allowable deviation of the output voltage during fast load transients also determines the output capacitance, its ESR, and its equivalent series inductance (ESL). The output capacitor supplies the load current during a load step until the controller responds with a greater duty cycle. The response time (tresponse) depends on the closed-loop bandwidth of the converter (see the Compensation Design section). The resistive drop across the output capacitors ESR, the drop across the capacitors ESL ( $\Delta V_{ESL}$ ), and the capacitor discharge causes a voltage droop during the loadstep. Use a combination of low-ESR tantalum/aluminum electrolyte and ceramic capacitors for better transient load and voltage ripple performance. Nonleaded capacitors and capacitors in parallel help reduce the ESL. Keep the maximum output voltage deviation below the tolerable limits of the electronics being powered. Use the following equations to calculate the required ESR, ESL, and capacitance value during a load step:

$$ESR = \frac{\Delta V_{ESR}}{I_{STEP}}$$

$$C_{OUT} = \frac{I_{STEP} \times t_{RESPONSE}}{\Delta V_Q}$$

$$ESL = \frac{\Delta V_{ESL} \times t_{STEP}}{I_{STEP}}$$

where ISTEP is the load step, tSTEP is the rise time of the load step, and tRESPONSE is the response time of the controller.

#### **Compensation Design**

The MAX5080/MAX5081 use a voltage-mode control scheme that regulates the output voltage by comparing the error amplifier output (COMP) with an internal ramp to produce the required duty cycle. The output lowpass LC filter creates a double pole at the resonant frequency, which has a gain drop of -40dB/decade. The error amplifier must compensate for this gain drop and phase shift to achieve a stable closed-loop system.

The basic regulator loop consists of a power modulator, an output feedback divider, and a voltage error amplifier. The power modulator has a DC gain set by  $V_{IN}/V_{RAMP}$ , with a double pole and a single zero set by the output inductance (L), the output capacitance

(COUT) (C5 in the *Typical Application Circuit*) and its equivalent series resistance (ESR). The power modulator incorporates a voltage feed-forward feature, which automatically adjusts for variations in the input voltage resulting in a DC gain of 10. The following equations define the power modulator:

$$G_{MOD(DC)} = \frac{V_{IN}}{V_{RAMP}} = 10$$
$$f_{LC} = \frac{1}{2\pi\sqrt{L \times C_{OUT}}}$$
$$f_{ZESR} = \frac{1}{2\pi \times C_{OUT} \times ESR}$$

The switching frequency is internally set at 250kHz or can vary from 150kHz to 350kHz when driven with an external SYNC signal. The crossover frequency ( $f_C$ ), which is the frequency when the closed-loop gain is equal to unity, should be set at 15kHz or below therefore:

#### fc ≤15kHz

The error amplifier must provide a gain and phase bump to compensate for the rapid gain and phase loss from the LC double pole. This is accomplished by utilizing a type 3 compensator that introduces two zeroes and 3 poles into the control loop. The error amplifier has a low-frequency pole (fP1) near the origin.

The two zeros are at:

$$f_{Z1} = \frac{1}{2\pi \times R5 \times C7}$$
 and  $f_{Z2} = \frac{1}{2\pi \times (R6 + R3) \times C6}$ 

and the higher frequency poles are at:

$$f_{P2} = \frac{1}{2\pi \times R6 \times C6} \text{ and } f_{P3} = \frac{1}{2\pi \times R5 \times \left(\frac{C7 \times C8}{C7 + C8}\right)}$$

#### Compensation When fc < fzesr

Figure 3 shows the error amplifier feedback as well as its gain response for circuits that use low-ESR output capacitors (ceramic). In this case  $f_{ZESR}$  occurs after f<sub>C</sub>.

f<sub>Z1</sub> is set to 0.8 x f<sub>LC(MOD)</sub> and f<sub>Z2</sub> is set to f<sub>LC</sub> to compensate for the gain and phase loss due to the double pole. Choose the inductor (L) and output capacitor (C<sub>OUT</sub>) as described in the *Inductor and Output Capacitor Selection* section.

Figure 3. Error Amplifier Compensation Circuit (Closed-Loop and Error-Amplifier Gain Plot) for Ceramic Capacitors

Pick a value for the feedback resistor R5 in Figure 3 (values between  $1k\Omega$  and  $10k\Omega$  are adequate). C7 is then calculated as:

$$C7 = \frac{1}{2\pi \times 0.8 \times f_{LC} \times R5}$$

fc occurs between fz<sub>2</sub> and fp<sub>2</sub>. The error-amplifier gain (GEA) at fc is due primarily to C6 and R5. Therefore, GEA(fC) =  $2\pi \times f_C \times C6 \times R5$  and the modulator gain at fc is:

$$G_{\text{MOD(fC)}} = \frac{G_{\text{MOD(DC)}}}{(2\pi)^2 \times L \times C_{\text{OUT}} \times f_{\text{C}}^2}$$

Since  $G_{EA(fC)} \times G_{MOD(fC)} = 1$ , C6 is calculated by:

$$C6 = \frac{f_{C} \times L \times C_{OUT} \times 2\pi}{R5 \times G_{MOD(DC)}}$$

 $f_{P2}$  is set at 1/2 the switching frequency (f\_SW). R6 is then calculated by:

$$R6 = \frac{1}{2\pi \times C6 \times 0.5 \times f_{SW}}$$

Since R3 >> R6, R3 + R6 can be approximated as R3. R3 is then calculated as:

$$R3 \approx \frac{1}{2\pi \times f_{LC} \times C6}$$

fp3 is set at 5xfc. Therefore C8 is calculated as:

$$C8 = \frac{C7}{(2\pi \times C7 \times R5 \times f_{P3} - 1)}$$

#### Compensation When fc > fzesr

For larger ESR capacitors such as tantalum and aluminum electrolytic ones, f<sub>ZESR</sub> can occur before f<sub>C</sub>. If f<sub>ZESR</sub> < f<sub>C</sub>, then f<sub>C</sub> occurs between f<sub>P2</sub> and f<sub>P3</sub>. f<sub>Z1</sub> and f<sub>Z2</sub> remain the same as before however, f<sub>P2</sub> is now set equal to f<sub>ZESR</sub>. The output capacitor's ESR zero frequency is higher than f<sub>LC</sub> but lower than the closedloop crossover frequency. The equations that define the error amplifier's poles and zeroes (f<sub>Z1</sub>, f<sub>Z2</sub>, f<sub>P1</sub>, f<sub>P2</sub>, and f<sub>P3</sub>) are the same as before. However, f<sub>P2</sub> is now lower than the closed-loop crossover frequency. Figure 4 shows the error amplifier feedback as well as its gain response for circuits that use higher-ESR output capacitors (tantalum or aluminum electrolytic).

Pick a value for the feedback resistor R5 in Figure 4 (values between  $1k\Omega$  and  $10k\Omega$  are adequate).

C7 is then calculated as:

$$C7 = \frac{1}{2\pi \times 0.8 \times f_{LC} \times R5}$$

The error amplifier gain between  $f_{P2}$  and  $f_{P3}$  is approximately equal to R5/R6 (given that R6 << R3). R6 can then be calculated as:

$$R6 \approx \frac{R5 \times 10 \times f_{LC}^2}{f_C^2}$$

C6 is then calculated as:

$$C6 = \frac{C_{OUT} \times ESR}{R6}$$

Figure 4. Error Amplifier Compensation Circuit (Closed-Loop and Error Amplifier Gain Plot) for Higher ESR Output Capacitors

Since R3 >> R6, R3 + R6 can be approximated as R3. R3 is then calculated as:

$$R3 \approx \frac{1}{2\pi \times f_{1,C} \times C6}$$

fp3 is set at 5xfc. Therefore, C8 is calculated as:

$$C8 = \frac{C7}{(2\pi \times C7 \times R5 \times f_{P3} - 1)}$$

#### **Power Dissipation**

The MAX5080/MAX5081 is available in a thermally enhanced package and can dissipate up to 2.7W at T<sub>A</sub> =  $+70^{\circ}$ C. When the die temperature reaches  $+160^{\circ}$ C, the part shuts down and is allowed to cool. After the parts cool by 20°C, the device restarts with a soft-start. The power dissipated in the device is the sum of the power dissipated from supply current ( $P_Q$ ), transition losses due to switching the internal power MOSFET ( $P_{SW}$ ), and the power dissipated due to the RMS current through the internal power MOSFET ( $P_{MOSFET}$ ). The total power dissipated in the package must be limited such that the junction temperature does not exceed its absolute maximum rating of +150°C at maximum ambient temperature. Calculate the power lost in the MAX5080/MAX5081 using the following equations:

#### The power loss through the switch:

$$P_{MOSFET} = I_{RMS}MOSFET^{2} \times R_{ON}$$

$$I_{RMS}MOSFET} = \sqrt{\left[I^{2}_{PK} + (I_{PK} \times I_{DC}) + I^{2}_{DC}\right] \times \frac{D}{3}}$$

$$I_{PK} = I_{OUT} + \frac{\Delta I_{P-P}}{2}$$

$$I_{DC} = I_{OUT} - \frac{\Delta I_{P-P}}{2}$$

R<sub>ON</sub> is the on-resistance of the internal power MOSFET (see *Electrical Characteristics*).

The power loss due to switching the internal MOSFET:

$$P_{SW} = \frac{V_{IN} \times I_{OUT} \times (t_R \times t_F) \times f_{SW}}{4}$$

where  $t_R$  and  $t_F$  are the rise and fall times of the internal power MOSFET measured at LX.

The power loss due to the switching supply current (Isw):

$$P_Q = V_{IN} \times I_{SW}$$

The total power dissipated in the device will be:

$$PTOTAL = PMOSFET + PSW + PQ$$
