

# Sup/IRBuck™

## 8A HIGHLY INTEGRATED WIDE-INPUT VOLTAGE, SYNCHRONOUS BUCK REGULATOR

### Features

- Input Voltage Range: 3V to 26V
- Output Voltage Range: 0.5V to 12V
- Continuous 8A Load Capability
- Constant On-Time control
- Excellent Efficiency at very low output current levels
- Compensation Loop not required
- Programmable switching frequency, soft start, and over current protection
- Power Good Output
- Precision Voltage Reference (0.5V, +/-1%)
- Pre-bias Start Up
- Under/Over Voltage Fault Protection
- Ultra small, low profile 5 x 6mm QFN Package

### Applications

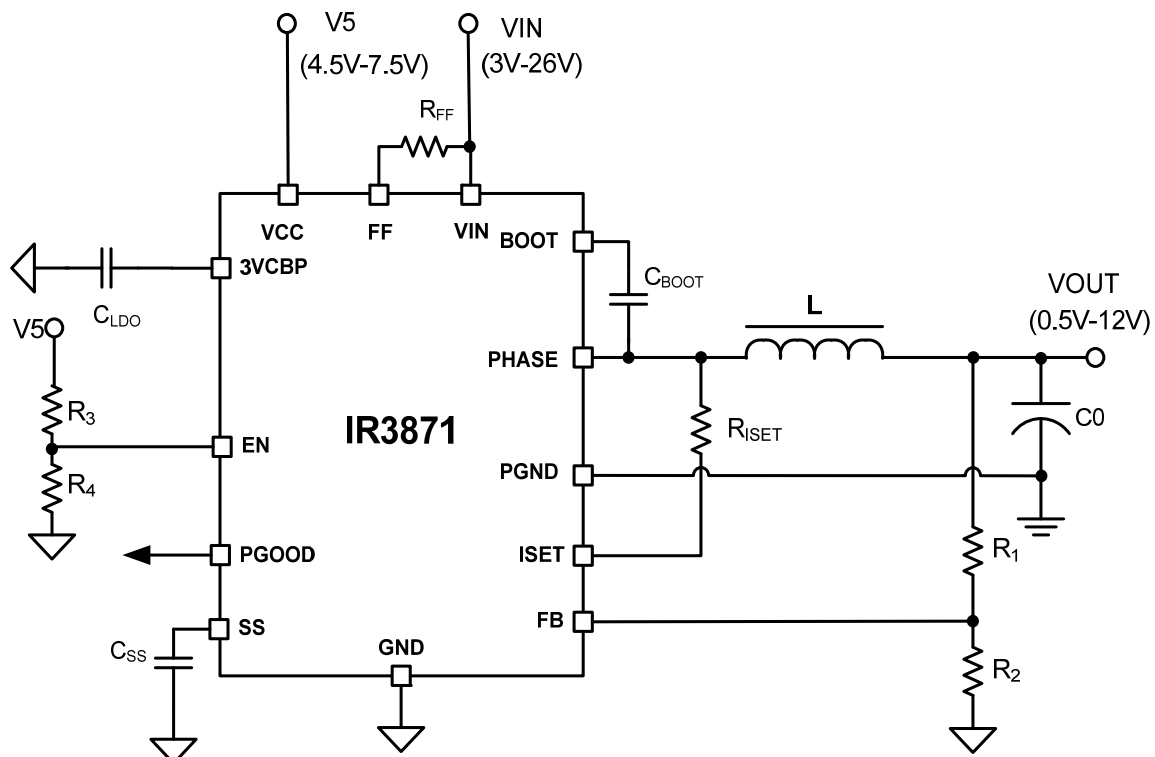

- Notebook and desktop computers
- Game consoles
- Consumer electronics – STB, LCD, TV, printers
- General purpose POL DC-DC converters

### Description

The IR3871 **SupIRBuck™** is an easy-to-use, fully integrated and highly efficient DC/DC voltage regulator. The onboard constant on time hysteretic controller and MOSFETs make IR3871 a space-efficient solution that delivers up to 8A of precisely controlled output voltage in 60°C ambient temperature applications without airflow.

Programmable switching frequency, soft start, and over current protection allows for a very flexible solution suitable for many different applications and an ideal choice for battery powered applications.

Additional features include pre-bias startup, very precise 0.5V reference, over/under voltage shut down, power good output, and enable input with voltage monitoring capability.

## ABSOLUTE MAXIMUM RATINGS

(Voltages referenced to GND unless otherwise specified)

- VIN, FF ..... -0.3V to 30V
- VCC, PGood, EN ..... -0.3V to 8.0V
- Boot ..... -0.3V to 40V
- PHASE ..... -0.3V to 30V(DC), -5V(100ns)
- Boot to PHASE ..... -0.3V to 8V
- ISET ..... -0.3V to 30V
- PGND to GND ..... -0.3V to +0.3V
- All other pins ..... -0.3V to 3.9V
- Storage Temperature Range ..... -65°C To 150°C
- Junction Temperature Range ..... -40°C To 150°C
- ESD Classification ..... JEDEC Class 1C
- Moisture sensitivity level ..... JEDEC Level 3@260 °C

*Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications are not implied.*

## PACKAGE INFORMATION

5mm x 6mm POWER QFN

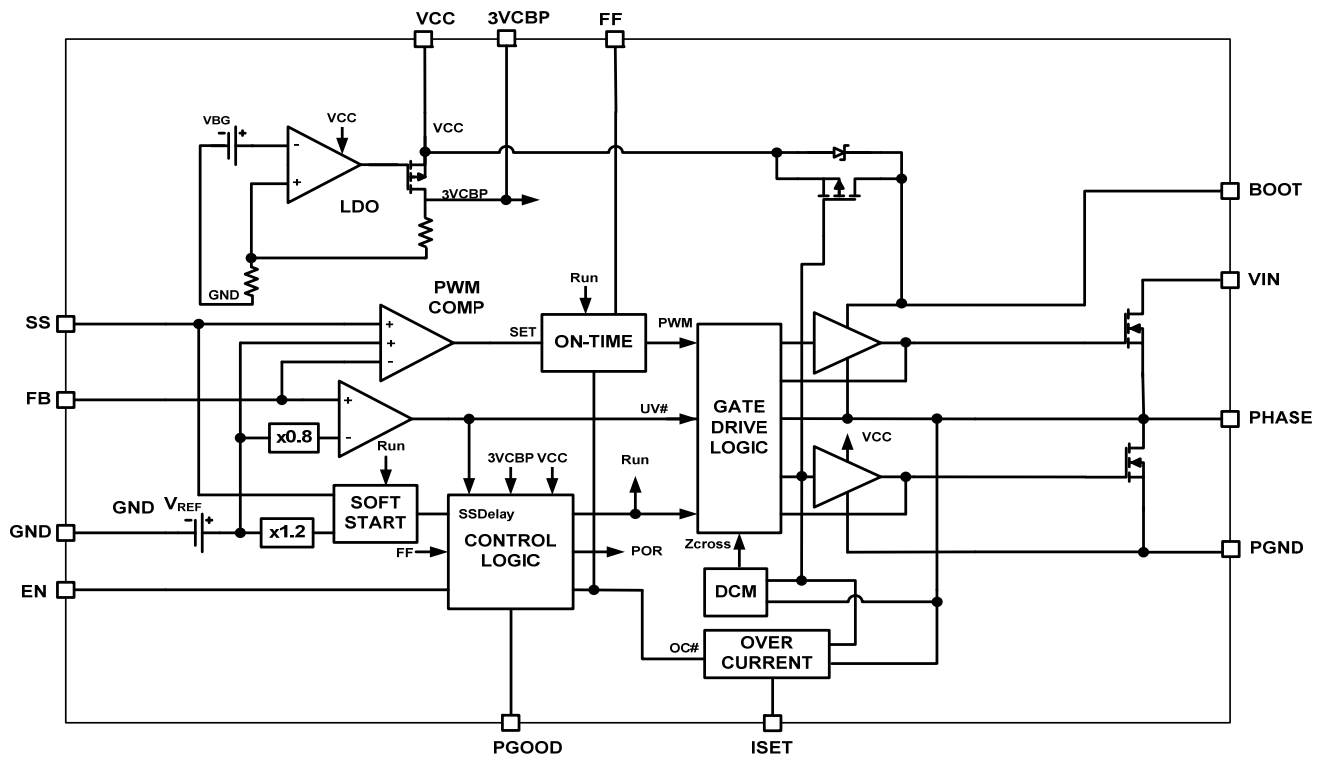

$$\theta_{JA} = 35^{\circ}\text{C} / \text{W}$$

$$\theta_{J-PCB} = 2^{\circ}\text{C} / \text{W}$$

## ORDERING INFORMATION

PKG DESIG	PACKAGE DESCRIPTION	PIN COUNT	PARTS PER REEL
M	IR3871MTRPbF	17	4000
M	IR3871TR1PbF	17	750

## Block Diagram

## Pin Description

NAME	NUMBER	I/O LEVEL	DESCRIPTION
NC	1	-----	No connection
ISET	2		Connecting resistor to PHASE pin sets over current trip point
PGOOD	3	5V	Power good open drain output – pull up with a resistor to 3.3V
GND	4,17	Reference	Bias return and signal reference
FB	5	3.3V	Inverting input to PWM comparator, OVP / PGood sense
SS	6	3.3V	Set soft start slew-rate with a capacitor to GND
NC	7	-----	No connection
3VCBP	8	3.3V	LDO output. A minimum of 1.0 $\mu$ F ceramic capacitor is required
NC	9	-----	No connection
VCC	10	5V	Gate drive supply
PGND	11	Reference	Power return
PHASE	12	VIN	Phase node (or switching node) of MOSFET half bridge
VIN	13	VIN	Input voltage for the system.
BOOT	14	VIN +VCC	Bootstrapped gate drive supply – connect a capacitor to PHASE
FF	15	VIN	Input voltage feed forward – sets on-time with a resistor to VIN
EN	16	5V	Enable

## Recommended Operating Conditions

## CIRCUIT DESCRIPTION

### PWM COMPARATOR

The PWM comparator initiates a SET signal (PWM pulse) when the FB pin falls below the reference (VREF) or the soft start (SS) voltage.

### ON-TIME GENERATOR

The PWM on-time duration is programmed with an external resistor (RFF) from the input supply (VIN) to the FF pin. The simplified equation for RFF is shown in equation 1. The FF pin is held to an internal reference after EN goes HIGH. A copy of the current in RFF charges a timing capacitor, which sets the on-time duration, as shown in equation 2.

$$R_{FF} = \frac{V_{OUT}}{1V \cdot 20pF \cdot F_{SW}} \quad (1)$$

$$T_{ON} = \frac{R_{FF} \cdot 1V \cdot 20pF}{V_{IN}} \quad (2)$$

### SOFT START

An internal 10µA current source charges the external capacitor on the SS pin to set the output voltage slew rate during the soft start interval. The output voltage reaches regulation when the FB pin is above the under voltage threshold and the UV# = HIGH. Once the voltage on the SS pin is above the PGOOD delay threshold, the combination of the SSDelay and UV# signals release the PGOOD pin. With EN = LOW, the capacitor voltage and SS pin is held to the FB pin voltage.

### CONTROL LOGIC

The control logic monitors input power sources, sequences the converter through the soft-start and protective modes, and indicates output voltage status on the PGOOD pin. VCC and 3VCBP pins are continuously monitored, and the IR3871 will be disabled if the voltage of either pin drops below the falling thresholds.

The IR3871 will initiate a soft start when VCC is in the normal range and the EN pin = HIGH. In the event of a sustained overload, a counter keeps track of four soft-start cycles and then disables the IR3871. The overload counter is only reset by EN or UVLO.

### GATE DRIVE LOGIC

The gate drive logic features adaptive dead time, diode emulation, and a minimum lower gate interval.

An adaptive dead time prevents the simultaneous conduction of the upper and lower MOSFETs. The lower gate voltage (LGATE) must be below approximately 1V after PWM goes HIGH before the upper MOSFET can be gated on. Also, the upper gate voltage (UGATE), the difference voltage between UGATE and PHASE, must be below approximately 1V after PWM goes LOW before the lower MOSFET can be gated on.

The control MOSFET is gated on after the adaptive delay for PWM = HIGH and the synchronous MOSFET is gated on after the adaptive delay for PWM = LOW. The lower MOSFET is driven 'off' when the signal ZCROSS indicates that the inductor current has reversed as detected by the PHASE voltage crossing the zero current threshold. The synchronous MOSFET stays 'off' until the next PWM falling edge. When the lower peak of inductor current is above zero, a forced continuous current condition is selected. The control MOSFET is gated on after the adaptive delay for PWM = HIGH, and the synchronous MOSFET is gated on after the adaptive delay for PWM = LOW.

The synchronous MOSFET gate is driven on for a minimum duration. This minimum duration allows time to recharge the bootstrap capacitor and allows the current monitor to sample the PHASE voltage.

## CIRCUIT DESCRIPTION

### OVER CURRENT MONITOR

The over current circuitry monitors the output current during each switching cycle. The voltage across the synchronous MOSFET, VPHASE, is monitored for over current and zero crossing. The minimum LGATE interval allows time to sample VPHASE.

The over current trip point is programmed with a resistor from the ISET pin to PHASE pin, as shown in equation 3, where  $T_j$  is the junction temperature of Q2 at operation conditions, and 0.4 is the temperature coefficient (~4000 ppm/°C) of Q2  $R_{DS(on)}$ . When over current is detected, the output gates are tri-state and SS voltage is pulled to 0V. This initiates a new soft start cycle. If there was a total of three OC events, the IR3871 will disable switching. Toggling VCC or EN will allow the next start up.

$$R_{SET} = \frac{R_{DS(on)} \cdot I_{OC}}{20 \mu A} \cdot \left(1 + \frac{T_j - 25}{100} \cdot 0.4\right) \quad (3)$$

### OVER VOLTAGE PROTECTION

The IR3871 monitors the voltage at the FB node. If the FB voltage is above the over voltage threshold, the gates are turned off and the PGOOD signal is pulled low. Toggling VCC will allow the next start up.

### STABILITY CONSIDERATIONS

Constant-on-time control is a fast, ripple based control scheme. Unstable operation can occur if certain conditions are not met. The system instability is usually caused by:

- Switching noise coupled to FB input. This causes the PWM comparator to trigger prematurely after the 400ns minimum Q2 on-time. It will result in double or multiple pulses every switching cycle instead of the expected single pulse. Double pulsing can cause higher output voltage ripple, but in most applications it will not affect operation. This can usually be prevented by careful layout of the ground plane and the FB sensing trace.
- Steady state ripple on FB pin being too small. The PWM comparator in IR3871 requires minimum 7mVp-p ripple voltage to operate stably. Not enough ripple will result in similar double pulsing issue described above. Solving this may require using output capacitors with higher ESR. Another way to solve this is to add a ~10pF ceramic capacitor from Vout to FB to couple more Vout ripple to the FB pin.
- ESR loop instability. The stability criteria of constant on-time is:  $ESR \cdot C_{out} > T_{on}/2$ . If ESR is too small that this criteria is violated then sub-harmonic oscillation will occur. This is similar to the instability problem of peak-current-mode control with  $D > 0.5$ . Increasing ESR is the most effective way to stabilize the system, but the price paid is the larger output voltage ripple.
- For applications with all ceramic output capacitors, the ESR is usually too small to meet the stability criteria. In these applications, external slope compensation is necessary to make the loop stable. The ramp injection circuit, composed of R6, C13, and C14, shown in Figure 7 is required. The inductor current ripple sensed by R6 and C13 is AC coupled to the FB pin through C14. The injected ramp slope can be adjusted by changing the RC time constant of R6 and C13, which is similar to the circuit used for DCR current sensing. C14 is typically chosen by  $C14 \cdot (R7/R8) = T_{on}$ .

## CIRCUIT DESCRIPTION

### COMPONENT SELECTION

Selection of components for the converter is an iterative process which involves meeting the specifications and trade-offs between performance and cost. The following sections will guide one through the process.

#### Inductor Selection

Inductor selection involves meeting the steady state output ripple requirement, minimizing the switching loss of upper MOSFETs, meeting transient response specifications and minimizing the output capacitance. The output voltage includes a DC voltage and a small AC ripple component due to the low pass filter which has incomplete attenuation of the switching harmonics. Neglecting the inductance in series with the output capacitor, the magnitude of the AC voltage ripple is determined by the total inductor ripple current flowing through the total equivalent series resistance (ESR) of the output capacitor bank.

$$\Delta I = \frac{T_{ON} \cdot (V_{IN} - V_{OUT})}{2 \cdot L} \quad (4)$$

One can use equation 4 to find the required inductance.  $\Delta I$  is defined as shown in Figure 18. The main advantage of small inductance is increased inductor current slew rate during a load transient, which leads to a smaller output capacitance requirement as discussed in the *Output Capacitor Selection* section. The drawback of using smaller inductances is increased switching power loss in upper MOSFET, which reduces the system efficiency and increases the thermal dissipation.

#### Input Capacitor Selection

The main function of the input capacitor bank is to provide the input ripple current and fast slew rate current during the load current step up. The input capacitor bank must have adequate ripple current carrying capability to handle the total RMS current. Figure 18 shows a typical input current. Equation 5 shows the RMS input current. The RMS input current contains the DC load current and the inductor ripple current. As shown in equation 4, the inductor ripple current is unrelated to the load current. The maximum RMS input current occurs at the maximum output current. The maximum power dissipation in the input capacitor equals the square of the maximum RMS input current times the input capacitor's total ESR.

Figure 18. Typical Input Current Waveform.

$$\begin{aligned} I_{IN\_RMS} &= \sqrt{\frac{1}{T_s} \cdot \int_0^{T_s} i^2(t) \cdot dt} \\ &= I_{OUT} \cdot \sqrt{T_{on} \cdot F_s} \cdot \sqrt{1 + \frac{1}{3} \cdot \left( \frac{\Delta I}{I_{OUT}} \right)^2} \quad (5) \end{aligned}$$

The voltage rating of the input capacitor needs to be greater than the maximum input voltage because of high frequency ringing at the phase node. The typical percentage is 25%.

### Output Capacitor Selection

Selection of the output capacitor requires meeting voltage overshoot requirements during load removal, and meeting steady state output ripple voltage requirements. The output capacitor is the most expensive converter component and increases the overall system cost. The output capacitor decoupling in the converter typically includes the low frequency capacitor, such as Specialty Polymer Aluminum, and mid frequency ceramic capacitors.

The first purpose of output capacitors is to provide current when the load demand exceeds the inductor current, as shown in Figure 19. Equation 6 shows the charge requirement for a certain load. The advantage provided by the IR3871 at a load step is to reduce the delay compared to a fixed frequency control method (in microseconds or  $(1-D) \cdot T_s$ ). If the load increases right after the PWM signal goes low, the longest delay will be equal to the minimum lower gate on as shown in the *Electrical Specification* table. The IR3871 also reduces the inductor current slew time, the time it takes for the inductor current to reach equality with the output current, by increasing the switching frequency up to 2.5MHz. The result reduces the recovery time.

Figure 19. Charge Requirement during Load Step

$$Q = C \cdot V = 0.5 \cdot I_{STEP} \cdot \Delta t \quad (6a)$$

$$C_{OUT} = \frac{1}{V_{DROP}} \left[ \frac{1}{2} \cdot \frac{L \cdot \Delta I_{STEP}^2}{(V_{IN} - V_{OUT})} \right] \quad (6b)$$

The output voltage drop,  $V_{DROP}$ , initially depends on the characteristic of the output capacitor.  $V_{DROP}$  is the sum of the equivalent series inductance (ESL) of the output capacitor times the rate of change of the output current and the ESR times the change of the output current.

$V_{ESR}$  is usually much greater than  $V_{ESL}$ . The IR3871 requires a total ESR such that the ripple voltage at the FB pin is greater than 7mV.

The second purpose of the output capacitor is to minimize the overshoot of the output voltage when the load decreases as shown in Figure 20. By using the law of energy before and after the load removal, equation 7 shows the output capacitance requirement for a load step.

$$C_{OUT} = \frac{L \cdot I_{STEP}^2}{V_{OS}^2 - V_{OUT}^2} \quad (7)$$

Figure 20. Typical Output Voltage Response Waveform.

### Boot Capacitor Selection

The boot capacitor starts the cycle fully charged to a voltage of  $V_B(0)$ .  $C_g$  equals 0.65nF in IR3871. Choose a sufficiently small  $\Delta V$  such that  $V_B(0) - \Delta V$  exceeds the maximum gate threshold voltage to turn on the high side MOSFET.

$$C_{BOOT} = C_g \cdot \left( \frac{V_B(0)}{\Delta V} - 1 \right) \quad (8)$$

Choose a boot capacitor value larger than the calculated  $C_{BOOT}$  in equation 8. Equation 8 is based on charge balance at CCM operation. Usually the boot capacitor will be discharged to a much lower voltage when the circuit is operating in DCM mode at light load, due to much longer Q2 off time and the bias current drawn by the IC. Boot capacitance needs to be increased if insufficient turn-on of Q1 is observed at light load, typically larger than 0.1μF is needed. The voltage rating of this part needs to be larger than  $V_B(0)$  plus the desired derating voltage. Its ESR and ESL needs to be low in order to allow it to deliver the large current and  $di/dt$ 's which drive MOSFETs most efficiently. In support of these requirements a ceramic capacitor should be chosen.

## DESIGN EXAMPLE

### Design Criteria:

Input Voltage,  $V_{IN}$ , = 6V to 21V  
 Output Voltage,  $V_{OUT}$  = 1.25V  
 Switching Frequency,  $F_S$  = 400KHz  
 Inductor Ripple Current,  $2\Delta I$  = 3A  
 Maximum Output Current,  $I_{OUT}$  = 6A  
 Over Current Trip,  $I_{OC}$  = 9A  
 Overshoot Allowance,  $V_{OS}$  =  $V_{OUT}$  + 50mV  
 Undershoot Allowance,  $V_{DROP}$  = 50mV

Find  $R_{FF}$ :

$$R_{FF} = \frac{1.25V}{1V \cdot 20pF \cdot 400KHz} = 156 K\Omega$$

Pick a standard value 158 k $\Omega$ , 1% resistor.

Find  $R_{SET}$ :

$$R_{SET} = \frac{1.4 \cdot 10m\Omega \cdot 9A}{20\mu A} = 6.3K\Omega$$

The  $R_{DS(on)}$  of the lower MOSFET could be expected to increase by a factor of 1.4 over temperature. Therefore, pick a 6.49k $\Omega$ , 1% standard resistor.

Find a resistive voltage divider for  $V_{OUT}$  = 1.25V:

$$V_{FB} = \frac{R_2}{R_2 + R_1} \cdot V_{OUT} = 0.5V$$

$R_2$  = 1.33k $\Omega$ ,  $R_1$  = 1.96 k $\Omega$ , both 1% standard resistors.

Choose the soft start capacitor:

Once the soft start time has chosen, such as 1000us to reach to the reference voltage, a 22nF for CSS is used to meet 1000us.

Choose an inductor to meet the design specification:

$$\begin{aligned} L &= \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN} \cdot 2\Delta I \cdot F_s} \\ &= \frac{1.25V \cdot (21V - 1.25V)}{21V \cdot 3A \cdot 400KHz} \\ &= 1.0\mu H \end{aligned}$$

Choose an inductor with the lowest DCR and AC power loss as possible to increase the overall system efficiency. For instance, choose an FDU0650-R82M manufactured by TOKO. The inductance of this part is 820nH and has 4.2m $\Omega$  DCR. Ripple current needs to be recalculated using the chosen inductor.

$$\Delta I = \frac{1.25V \cdot (21V - 1.25V)}{2 \cdot 21V \cdot 0.82\mu H \cdot 400KHz} = 1.75A$$

Choose an input capacitor:

$$I_{IN\_RMS} = 6A \cdot \sqrt{\frac{1.25V}{21V}} \cdot \sqrt{1 + \frac{1}{3} \cdot \left(\frac{1.75A}{6A}\right)^2} = 1.5A$$

A Panasonic 10 $\mu$ F (ECJ3YB1E106M) accommodates 6 Arms of ripple current at 300KHz. Due to the chemistry of multilayer ceramic capacitors, the capacitance varies over temperature and operating voltage, both AC and DC. One 10 $\mu$ F capacitor is recommended. In a practical solution, one 1 $\mu$ F capacitor is required along with 10 $\mu$ F. The purpose of the 1 $\mu$ F capacitor is to suppress the switching noise and deliver high frequency current.

Choose an output capacitor:

To meet the undershoot specification, select a set of output capacitors which has an equivalent ESR of 10m $\Omega$  (50mV/5A). To meet the overshoot specification, equation 7 will be used to calculate the minimum output capacitance. As a result, 160 $\mu$ F will be needed for 5A load remover. Combine those two requirements, one can choose a set of output capacitors from manufactures such as SP-Cap (Specialty Polymer Capacitor) from Panasonic or POSCAP from Sanyo. A 150 $\mu$ F (EEFSL0D151R) from Panasonic is recommended. This capacitor has 9m $\Omega$  ESR which leaves margin for the voltage drop of the ESL during load step up. The typical ESL for this capacitor is around 2nH.

## LAYOUT RECOMMENDATION

### **Bypass Capacitor:**

One 1 $\mu$ F high quality ceramic capacitor should be placed as near VCC pin as possible. The other end of capacitor can be connected to a via or connected directly to GND plane. Use a GND plane instead of a thin trace to the GND pin because a thin trace have too much impedance.

### **Boot Circuit:**

C<sub>BOOT</sub> should be placed near the BOOT and PHASE pins to reduce the impedance when the upper MOSFET turns on.

### **Power Stage:**

Figure 21 shows the current paths and their directions for the on and off periods. The on time path has low average DC current and high AC current. Therefore, it is recommended to place the input ceramic capacitor, upper, and lower MOSFET in a tight loop as shown in Figure 21.

The purpose of the tight loop from the input ceramic capacitor is to suppress the high frequency (10MHz range) switching noise and reduce Electromagnetic Interference (EMI). If this path has high inductance, the circuit will cause voltage spikes and ringing, and increase the switching loss. The off time path has low AC and high average DC current. Therefore, it should be laid out with a tight loop and wide trace at both ends of the inductor. Lowering the loop resistance reduces the power loss. The typical resistance value of 1-ounce copper thickness is 0.5m $\Omega$  per square inch.

### PCB Metal and Components Placement

Lead lands (the 13 IC pins) width should be equal to nominal part lead width. The minimum lead to lead spacing should be  $\geq 0.2\text{mm}$  to minimize shorting.

Lead land length should be equal to maximum part lead length + 0.3 mm outboard extension. The outboard extension ensures a large toe fillet that can be easily inspected.

Pad lands (the 4 big pads) length and width should be equal to maximum part pad length and width. However, the minimum metal to metal spacing should be no less than; 0.17mm for 2 oz. Copper or no less than 0.1mm for 1 oz. Copper or no less than 0.23mm for 3 oz. Copper.

Component Pad

## Solder Resist

It is recommended that the lead lands are Non Solder Mask Defined (NSMD). The solder resist should be pulled away from the metal lead lands by a minimum of 0.025mm to ensure NSMD pads.

The land pad should be Solder Mask Defined (SMD), with a minimum overlap of the solder resist onto the copper of 0.05mm to accommodate solder resist misalignment.

Ensure that the solder resist in between the lead lands and the pad land is  $\geq 0.15\text{mm}$  due to the high aspect ratio of the solder resist strip separating the lead lands from the pad land.

PCB Solder Resist

## Stencil Design

The Stencil apertures for the lead lands should be approximately 80% of the area of the lead lands. Reducing the amount of solder deposited will minimize the occurrences of lead shorts. If too much solder is deposited on the center pad the part will float and the lead lands will open.

The maximum length and width of the land pad stencil aperture should be equal to the solder resist opening minus an annular 0.2mm pull back in order to decrease the risk of shorting the center land to the lead lands when the part is pushed into the solder paste.
