## Switched-Capacitor Voltage Inverters

## General Description

The ultra-small MAX828/MAX829 monolithic, CMOS charge-pump inverters accept input voltages ranging from +1.5 V to +5.5 V . The MAX828 operates at 12 kHz , and the MAX829 operates at 35 kHz . Their high efficiency (greater than $90 \%$ over most of the load-current range) and low operating current (60 1 A for the MAX828) make these devices ideal for both battery-powered and boardlevel voltage-conversion applications.
The MAX828/MAX829 combine low quiescent current and high efficiency. Oscillator control circuitry and four power MOSFET switches are included on-chip. Applications include generating a -5 V supply from $\mathrm{a}+5 \mathrm{~V}$ logic supply to power analog circuitry. Both parts come in a 5 -pin SOT23-5 package and can deliver 25 mA with a voltage drop of 500 mV .
For a similar device with logic-controlled shutdown, refer to the MAX1719/MAX1720/MAX1721. For applications requiring more power, the MAX860 delivers up to 50 mA with a voltage drop of 600 mV , in a space-saving $\mu \mathrm{MAX}$ package.

Applications
Small LCD Panels
Cell Phones
Medical Instruments
Handy-Terminals, PDAs
Battery-Operated Equipment

Typical Operating Circuit

- 5-Pin SOT23-5 Package
- 95\% Voltage Conversion Efficiency
- Inverts Input Supply Voltage
-601AA Quiescent Current (MAX828)
- +1.5V to +5.5V Input Voltage Range
- Requires Only Two Capacitors
- 25mA Output Current

Ordering Information

| PART | TEMP. RANGE | PIN- <br> PACKAGE | SOT <br> TOP MARK |
| :---: | :---: | :---: | :---: |
| MAX828EUK | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 5 SOT23-5 | AABI |
| MAX829EUK | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 5 SOT23-5 | AABJ |

ABSOLUTE MAXIMUM RATINGS <br> | IN to GND | V, -0.3V |
| :---: | :---: |
| OUT to GND | -6.0V, +0.3V |
| OUT Output Current | 50 mA |
| OUT Short-Circuit to GND | Indefinite |
| Continuous Power Dissipation ( $\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}$ ) |  |
| SOT23-5 (derate $7.1 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ) | 571 mW |

Operating Temperature Range
MAX828EUK/MAX829EUK .......................................... ${ }^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
Storage Temperature Range ${ }^{\circ} \mathrm{C}$ to $+160^{\circ} \mathrm{C}$
Lead Temperature (soldering, 10s) ................................... $+300^{\circ} \mathrm{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

$\left(\mathrm{VIN}=+5 \mathrm{~V}, \mathrm{C} 1=\mathrm{C} 2=10 \mu \mathrm{~F}\right.$ (MAX828) $, \mathrm{C} 1=\mathrm{C} 2=3.3 \mu \mathrm{~F}(\mathrm{MAX829}), \mathrm{T}_{\mathrm{A}}=0^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$, unless otherwise noted. Typical values are at $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$.)

| PARAMETER | CONDITIONS |  | MIN | TYP | MAX | UNITS |

## Switched-Capacitor Voltage Inverters

## Detailed Description

The MAX828/MAX829 capacitive charge pumps invert the voltage applied to their input. For highest performance, use low equivalent series resistance (ESR) capacitors.
During the first half-cycle, switches S2 and S4 open, switches S1 and S3 close, and capacitor C1 charges to the voltage at IN (Figure 2). During the second halfcycle, S1 and S3 open, S2 and S4 close, and C1 is level shifted downward by VIN volts. This connects C1 in parallel with the reservoir capacitor C2. If the voltage across C2 is smaller than the voltage across C1, then charge flows from C1 to C2 until the voltage across C2 reaches VIN. The actual voltage at the output is more positive than - $\mathrm{V}_{\mathrm{IN}}$, since switches S1-S4 have resistance and the load drains charge from C2.

## Charge-Pump Output

The MAX828/MAX829 are not voltage regulators: the charge pump's output source resistance is approximately $20 \Omega$ at room temperature (with $\mathrm{VIN}=+5 \mathrm{~V}$ ), and Vout approaches -5V when lightly loaded. VOUT will droop toward GND as load current increases. The droop of the negative supply (VDROOP-) equals the current draw from OUT (IOUT) times the negative converter's source resistance (RS-):

$$
\text { VDROOP- = IOUT } \times \text { RS- }
$$

The negative output voltage will be:

$$
\text { VOUT }=-(\text { VIN }- \text { VDROOP- })
$$

## Efficiency Considerations

The efficiency of the MAX828/MAX829 is dominated by its quiescent supply current (IQ) at low output current and by its output impedance (ROUT) at higher output current; it is given by:

$$
\eta \cong \frac{\mathrm{l}_{\text {OUT }}}{\mathrm{l}_{\text {OUT }}+\mathrm{I}_{\mathrm{Q}}}\left(1-\frac{\mathrm{l}_{\text {OUT }} \times \mathrm{R}_{\text {OUT }}}{\mathrm{V}_{\mathrm{IN}}}\right)
$$

Figure 3a. Switched-Capacitor Model

Figure 2. Ideal Voltage Inverter
where the output impedance is roughly approximated by:

$$
\mathrm{R}_{\mathrm{OUT}} \cong \frac{1}{\left(\mathrm{f}_{\mathrm{OSC}}\right) \times \mathrm{C} 1}+2 \mathrm{R}_{\mathrm{SW}}+4 \mathrm{ESR}_{\mathrm{C} 1}+\mathrm{ESR}_{\mathrm{C} 2}
$$

The first term is the effective resistance of an ideal switched-capacitor circuit (Figures 3a and 3b), and RSW is the sum of the charge pump's internal switch resistances (typically $8 \Omega$ to $9 \Omega$ at $\mathrm{VIN}=+5 \mathrm{~V}$ ). The typical output impedance is more accurately determined from the Typical Operating Characteristics.

## Applications Information <br> Capacitor Selection

To maintain the lowest output resistance, use capacitors with low ESR (Table 1). The charge-pump output resistance is a function of C1's and C2's ESR. Therefore, minimizing the charge-pump capacitor's ESR minimizes the total output resistance.

Figure 3b. Equivalent Circuit

# Switched-Capacitor Voltage Inverters 

Flying Capacitor (C1)
Increasing the flying capacitor's size reduces the output resistance. Small C1 values increase the output resistance. Above a certain point, increasing C1's capacitance has a negligible effect, because the output resistance becomes dominated by the internal switch resistance and capacitor ESR.

## Output Capacitor (C2)

Increasing the output capacitor's size reduces the output ripple voltage. Decreasing its ESR reduces both output resistance and ripple. Smaller capacitance values can be used with light loads if higher output ripple can be tolerated. Use the following equation to calculate the peak-to-peak ripple:

$$
\mathrm{V}_{\mathrm{RIPPLE}}=\frac{\mathrm{l}_{\mathrm{OUT}}}{\mathrm{f}_{\mathrm{OSC}} \times \mathrm{C} 2}+2 \times \mathrm{I}_{\mathrm{OUT}} \times \mathrm{ESR}_{\mathrm{C} 2}
$$

Input Bypass Capacitor
Bypass the incoming supply to reduce its AC impedance and the impact of the MAX828/MAX829's switching noise. The recommended bypassing depends on the circuit configuration and on where the load is connected.
When the inverter is loaded from OUT to GND, current from the supply switches between $2 \times$ IOUT and zero. Therefore, use a large bypass capacitor (e.g., equal to the value of C 1 ) if the supply has a high AC impedance.
When the inverter is loaded from IN to OUT, the circuit draws $2 \times$ IOUT constantly, except for short switching spikes. A $0.1 \mu \mathrm{~F}$ bypass capacitor is sufficient.

## Voltage Inverter

The most common application for these devices is a charge-pump voltage inverter (Figure 1). This application requires only two external components-capacitors C1 and C2-plus a bypass capacitor, if necessary. Refer to
the Capacitor Selection section for suggested capacitor types and values.

Cascading Devices
Two devices can be cascaded to produce an even larger negative voltage (Figure 4). The unloaded output voltage is normally $-2 \times \mathrm{V}$ IN, but this is reduced slightly by the output resistance of the first device multiplied by the quiescent current of the second. When cascading more than two devices, the output resistance rises dramatically. For applications requiring larger negative voltages, see the MAX864 and MAX865 data sheets.

## Paralleling Devices

Paralleling multiple MAX828s or MAX829s reduces the output resistance. Each device requires its own pump capacitor (C1), but the reservoir capacitor (C2) serves all devices (Figure 5). Increase C2's value by a factor of $n$, where $n$ is the number of parallel devices. The equation for calculating output resistance is also shown in Figure 5.

Combined Doubler/Inverter In the circuit of Figure 6, capacitors C 1 and C 2 form the inverter, while C3 and C4 form the doubler. C1 and C3 are the pump capacitors; C 2 and C 4 are the reservoir capacitors. Because both the inverter and doubler use part of the charge-pump circuit, loading either output causes both outputs to decline toward GND. Make sure the sum of the currents drawn from the two outputs does not exceed 40 mA .

## Table 1. Low-ESR Capacitor Manufacturers

| MANUFACTURER |  | PHONE | FAX | DEVICE TYPE |
| :---: | :---: | :---: | :---: | :---: |
| AVX |  | $\begin{aligned} & \text { (803) 946-0690 } \\ & \text { (800) 282-4975 } \end{aligned}$ | (803) 626-3123 | Surface-mount, TPS series |
| Matsuo |  | (714) 969-2491 | (714) 960-6492 | Surface-mount, 267 series |

## Heavy Output Current Loads

When under heavy loads, where higher supply is sourcing current into OUT, the OUT supply must not be pulled above ground. Applications that sink heavy current into OUT require a Schottky diode (1N5817) between GND and OUT, with the anode connected to OUT (Figure 7).

## Layout and Grounding

Good layout is important, primarily for good noise performance. To ensure good layout, mount all components as close together as possible, keep traces short to minimize parasitic inductance and capacitance, and use a ground plane.

Figure 7. High V-Load Current

## Shutting Down the MAX828/MAX829

For a similar device with logic-controlled shutdown, please refer to the MAX1719/MAX1720/MAX1721. To add manual shutdown control to the MAX828/MAX829, use the circuit in Figure 8. The output resistance of the MAX828/MAX829 will typically be $20 \Omega$ plus two times the output resistance of the buffer driving IN. The $0.1 \mu \mathrm{~F}$ capacitor at the IN pin absorbs the transient input currents of the MAX828/MAX829.
The output resistance of the buffer driving the IN pin can be reduced by connecting multiple buffers in parallel. The polarity of the SHUTDOWN signal can also be changed by using a noninverting buffer to drive IN.
