General Description

Micron’s FBDIMM devices adhere to the currently proposed industry specifications for FBDIMMs. The following specifications contain detailed information on FBDIMM design, interfaces, and theory of operation and are listed here for the system designers’ convenience. Refer to the JEDEC Web site for available specifications.

- FBDIMM Design Specification – pending JEDEC approval
- FBDIMM: Architecture and Protocol – JESD206
- FBDIMM: Advanced Memory Buffer (AMB) – JESD82-20
- Design for Test, Design for Validation (DFx) Specification
- Serial Presence-Detect (SPD) for Fully Buffered DIMM – JEDEC Standard No. 21-C, page 4.1.2.7-1

This DDR2 SDRAM module is a high-bandwidth, large-capacity channel solution that has a narrow host interface. FBDIMM devices use DDR2 SDRAM devices isolated from the channel behind an AMB buffer on the FBDIMM. Memory device capacity remains high, and total memory capacity scales with DDR2 SDRAM bit density.

As shown in the System Block Diagram, the FBDIMM channel provides a communication path from a host controller to an array of DDR2 SDRAM devices, with the DDR2 SDRAM devices buffered behind an AMB device. The physical isolation of the DDR2 SDRAM devices from the channel enhances the communication path and significantly increases the reliability and availability of the memory subsystem.

Advanced Memory Buffer

The AMB isolates the DDR2 SDRAM devices from the channel. This single-chip AMB component, located in the center of each FBDIMM, acts as a repeater and buffer for all signals and commands exchanged between the host controller and DDR2 SDRAM devices, including data input and output. The AMB communicates with the host controller and adjacent FBDIMMs on a system board using an industry-standard, high-speed, differential, 1.5V, point-to-point interface. The AMB also enables buffering of memory traffic to support large memory capacities. Refer to the JEDEC JESD82-20 specification for further information.

1. To avoid spurious start and stop conditions, a minimum delay is placed between SCL = 1 and the falling or rising edge of SDA.
 2. This parameter is sampled.
 3. For a restart condition, or following a WRITE cycle.
 4. The SPD EEPROM WRITE cycle time (t_{WRC}) is the time from a valid stop condition of a write sequence to the end of the EEPROM internal ERASE/PROGRAM cycle. During the WRITE cycle, the EEPROM bus interface circuit is disabled, SDA remains HIGH due to pull-up resistance, and the EEPROM does not respond to its slave address.
