

DESCRIPTION

The LXMG1618A-12-6xTM is a Single Output 6W Direct DriveTM CCFL (Cold Cathode Fluorescent Lamp) Inverter Module designed for driving LCD backlight lamps. It is ideal for driving typically 12.1" to 15" panels.

The maximum output current is externally programmable over a range of 5 to 8mA in 1mA steps (PanelMatch) to allow the inverter to properly match to a wide array of LCD panel lamp current specifications. The modules include a dimming input that permits brightness control from a DC voltage source, a PWM signal or an external potentiometer.

LXMG1618A modules unlike the LXMG1617A series do not provide wide range 'burst' mode dimming, rather dimming is provided by amplitude control of the output current waveform, and this limits the potential dim range to typically less than 5:1.

The module converts a DC voltage

from the system battery, or AC adapter directly to high frequency, high-voltage waveform required to ignite and operate CCFL lamps. A 5V input inverter is also available (LXMG1618A-05-6x).

The LXMG1618A modules contain the newer highly integrated LX1691B CCFL backlight controller to provide a wider temperature range (-30°C to 80°C) compared to the existing solutions offered by Microsemi.

Other benefits of the inverter's topology include stable fixed-frequency operation, secondary-side strike voltage regulation and both open/shorted lamp protection with fault timeout.

The new LXMG1618A ("A Series") modules are designed therefore as a higher performance near drop-in replacement (see BRITE minimum input) for those customers and applications currently using the LXMG1618 inverters.

KEY FEATURES

- Externally Programmable Maximum Output Current
- Easy to Use Brightness Control
- Output Short-Circuit Protection and Automatic Strike-Voltage Regulation and Timeout
- Analog Current Amplitude Dimming Method
- Fixed Frequency Operation
- Rated From -30 to 80°C
- UL60950 E175910
- RoHS Compliant

APPLICATIONS

- Medical Instrument Displays
- Portable Instrumentation
- Industrial Display Controls

BENEFITS

- Compact, Low Profile Design
- Mates to Wide Variety of LCD Panels
- Output Open Circuit Voltage Regulation Minimizes Corona Discharge For High Reliability

RECOMMENDED OPERATING CONDITIONS (R.C.)

This module has been designed to operate over a wide range of input and output conditions. However, best efficiency and performance will be obtained if the module is operated under the condition listed in the 'R.C.' column. Min. and Max. columns indicate values beyond which the inverter, although operational, may not function optimally.

Parameter	Symbol	Recommended Operating Conditions			Units
		Min	R.C.	Max	
Input Supply Voltage Range (Fully Regulated Lamp Current)	V_{IN}	10.8	12	13.2	V
Input Supply Voltage Range (Functional)		10.2	12	13.8	
Output Power	P_O			6.0	W
Linear BRITE Control Input Voltage Range ¹	V_{BRT_ADJ}	0		2.0	V

Lamp Current (Full Brightness)	I_{OLAMP}	5		8	mA_{RMS}
Operating Ambient Temperature Range	T_A	-30		80	°C

¹ The BRITE minimum input voltage level is 0V, whereas it is 0.65V in the original LXMG1618-12-6x inverter, see application info on page 5. The minimum V_{BRT_ADJ} voltage depends on the panel characteristics and minimum lamp current specification, depending on the panel it can vary from 0V to 0.5V

* Total output power must not exceed 6W. Higher voltage lamps may require maximum output current to be set lower than $8mA_{RMS}$

TYPICAL APPLICATION

Figure 1 – Brightness Control
(Output current set to maximum)

Figure 1A – PWM Brightness Control

Figure 2 – Max Output Current
(SET₁ and SET₂ Inputs)

- The brightness control may be a voltage output DAC or other voltage source, a digital pot or 500K manual pot. The inverter contains an internal 338K pull-up in series with 71.5k to 3V to bias the pot, if desired; add a resistor to set the lower threshold voltage above the absolute minimum dim level capability. A PWM logic level signal (figure 1A) may be used up to 5V; however the inverter will reach maximum current at less than 100% duty cycle. This can be calculated as approximately 2V divided by the logic high voltage level; with 3.3V logic level this corresponds to about 60% duty cycle for maximum lamp current.
- If you need to turn the inverter ON/OFF remotely, connect to TTL logic signal to the SLEEP input.
- Connect V_{HI} to high voltage wire from the lamp. Connect V_{LO} to the low voltage wire (wire with thinner insulation). Never connect V_{LO} to circuit ground as this will defeat lamp current regulation. If both lamp wires have heavy high voltage insulation, connect the longest wire to V_{LO}. This wire is typically white.
- Use the SET₁ and SET₂ (see Figure 2) inputs to select the desired maximum output current. Using these two pins in combination allows the inverter to match a wide variety of panels from different manufacturers. Generally the best lamp lifetime correlates with driving the CCFL at the manufacturer's nominal current setting. However the SET₁ and SET₂ inputs allow the user the flexibility to adjust the current to the maximum allowable output current to increase panel brightness at the expense of some reduced lamp life.
- Although the SET pins are designed such that just leaving them open or grounding them is all that is needed to set the output current, they can also be actively set. Using an open collector or open drain logic signal will allow you to reduce the lamp current for situations where greater dim range is required, as an example in nighttime situations. In conjunction with a light sensor or other timer the panel could be set to higher brightness (maximum output current) for daytime illumination and lower brightness (minimum or typical output current) at nighttime. Since the dim ratio is a factor of the peak output current, using this technique the effective dim ratio can be increased. Conversely, the SET inputs could be used to overdrive the lamp temporarily to facilitate faster lamp warm up at initial lamp turn on. Of course any possible degradation on lamp life from such practices is the user's responsibility since not all lamps are designed to be overdriven.
- The inverter has a built-in fault timeout function. If the output is open (lamp disconnected or broken) or shorted the inverter will attempt to strike the lamp up to about one second, after which (without success) the inverter will shutdown, in this mode the inverter will draw about 10mA from V_{IN}. In order to restart the inverter it is necessary to toggle the sleep input or cycle the V_{IN} input supply.
