

# LM3402/02HV Demo Board

National Semiconductor  
Application Note 1500  
Chris Richardson  
June 2007

## Introduction

The LM3402/LM3402HV is a buck regulator derived controlled current source designed to drive a series string of high power, high brightness LEDs (HBLEDs) such as the Luxeon™ I Emitter at forward currents of up to 500 mA. The board can accept an input voltage ranging from 6V to 42V when using the LM3402. When using the pin-for-pin compatible LM3402HV the upper bound of input voltage is 75V. The converter output voltage adjusts as needed to maintain a constant current through the LED array. The LM3402/02HV is a true step-down regulator with an output voltage range extending from a  $V_{O(MIN)}$  of 200 mV (the reference voltage) to a  $V_{O(MAX)}$  determined by the minimum off time (typically 300 ns). It can maintain regulated current through any number of LEDs as long as the combined forward voltage of the array does not exceed  $V_{O(MAX)}$ .

## Circuit Performance LM3402

The LM3402 circuit and BOM have been designed to provide a constant forward current of 350 mA to a single LED with a forward voltage of approximately 3.5V. (Typical of white, blue, and green LEDs using InGaN technology.) When powered from a  $24V \pm 5\%$  input the demo board will maintain the average LED current,  $I_F$ , to within 10% of 350 mA. The ripple current,  $\Delta i_F$ , will not exceed 70 mA peak-to-peak. Switching frequency for the demo board is  $600 \text{ kHz} \pm 10\%$  over the input voltage range of 6V to 42V.

## Circuit Performance LM3402HV

The LM3402HV circuit and BOM have been designed to provide a constant forward current of 350 mA to a single LED with a forward voltage of approximately 3.5V. When powered from a  $48V \pm 5\%$  input the demo board will maintain  $I_F$  to within  $\pm 5\%$  of 350 mA. Ripple current will not exceed 70 mA peak-to-peak. Switching frequency for the demo board is  $250 \text{ kHz} \pm 10\%$  over the input voltage range of 6V to 75V.

## Connecting to LED Array

The LM3402/02HV demo board includes a female 6-pin SIP, **J1**, connector as well as two standard 94mil turret connectors for the cathode and anode connections of the LED array. Figure 1 shows the pinout of **J1**. Solid, 18 or 20 gauge wire with about 1 cm of insulation stripped away makes a convenient, solderless connection to **J1**.

FIGURE 1.

## Setting the LED Current

The default forward current  $I_{LED}$  delivered to the LED array is 350 mA, typical of many 1W LEDs. To adjust this value the current setting resistor  $R_{SNS}$  can be changed according to the following equation:

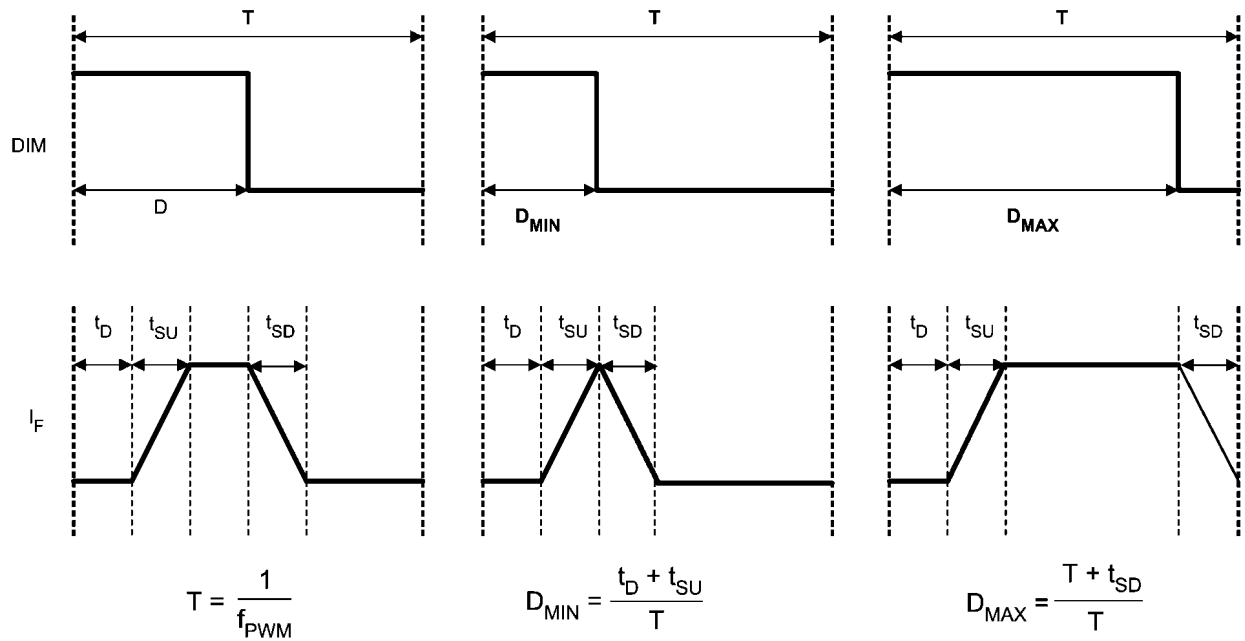

$$R_{SNS} = \frac{0.2 \times L}{I_F \times L + V_O \times t_{SNS} - \frac{V_{IN} - V_O}{2} \times t_{ON}}$$

$$t_{SNS} = 220 \text{ ns}$$

This resistor should be rated to handle the power dissipation of the LED current. For example, the closest 5% tolerance resistor to set an LED current of 350 mA is  $0.56 \Omega$ . In steady state this resistor will dissipate  $(0.352 \times 0.56) = 69 \text{ mW}$ , indicating that a resistor with a 1/8W power rating is appropriate.

## PWM Dimming

The **DIM1** terminal on the PCB provides an input for a pulse width modulation signal for dimming of the LED array. In order to fully enable and disable the LM3402/02HV the PWM signal should have a maximum logic low level of 0.8V and a minimum logic high level of 2.2V. The maximum PWM dimming frequency, minimum PWM duty cycle and maximum duty cycle are illustrated in Figure 2. PWM frequency should be at least one order of magnitude below the LM3402/02HV switching frequency. The interval  $t_D$  represents the delay from a logic high at the DIM pin to the onset of the output current. The quantities  $t_{SU}$  and  $t_{SD}$  represent the time needed for the output current to slew up to steady state and slew down to zero, respectively. Typical response times for the standard LM3402 and LM3402HV demo boards circuits are shown in the Typical Performance Characteristics section.

FIGURE 2. PWM Dimming Limits

The logic of **DIM1** is direct, hence the LM3402/02HV will deliver regulated output current when the voltage at **DIM1** is high, and the current output is disabled when the voltage at **DIM1** is low. Connecting a constant logic low will disable the output, and the LM3402/02HV is enabled if the DIM pin is open-circuited. The **DIM1** function disables only the power NFET, leaving all other circuit blocks functioning to minimize the converter response time.

The **DIM2** terminal provides a second method for PWM dimming by connecting to the gate of an optional NFET, **Q1**. Note that **Q1** is not provided on the standard BOM, and must be added for the **DIM2** function to operate. **Q1** provides a parallel path for the LED current. This small NFET can be turned on and off much more quickly than the LM3402/02HV can shut down the internal NFET, providing faster response time for higher frequency and/or greater resolution in the PWM dimming signal. The tradeoff in this method is that the full current flows through **Q1** while the LED is off, resulting in lower efficiency.

The logic of **DIM2** is inverted, hence the LM3402/02HV will deliver regulated output current when the voltage at **DIM2** is low, and the current output is disabled when the voltage at **DIM2** is high. Connecting a constant logic high to the **DIM2** will turn off the LED but will not shut down the LM3402/02HV.

## Low Power Shutdown

The LM3402/02HV can be placed into a low power shutdown (typically 90  $\mu$ A) by grounding the **OFF\*** terminal. During normal operation this terminal should be left open-circuit.

## Output Open Circuit

With either DIM terminal floating or connected to logic high, the LM3402/02HV will begin to operate as soon as it has an input of at least 6V. In the case that the input is powered but no LED array is connected the output voltage will rise to equal the input voltage. The output of the circuit is rated to 50V (LM3402) or 100V (LM3402HV) and will not suffer damage, however care should be taken not to connect an LED array if the output voltage is higher than the target forward voltage of the LED array in steady state. Alternatively, a zener diode and zener current limiting resistor can be placed in the positions **Z1** and **Rz**. In the case of an accidental open circuit at the output **Z1** will enter reverse bias and attempt to pull the CS pin voltage up to the output voltage. An internal comparator monitors the CS pin voltage and will disable the internal NFET in this case. The result is a low power hiccup mode, designed to prevent excessive voltage at the output and thermal stress on the inductor, internal NFET, and input voltage source.

### LIFE SUPPORT POLICY

**NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE CHIEF EXECUTIVE OFFICER AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION.** As used herein:

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.
