

## **16-BIT ROMLESS MCU**

- HIGH PERFORMANCE CPU
  - 16-BIT CPU WITH 4-STAGE PIPELINE
  - 80ns INSTRUCTION CYCLE TIME @ 25MHz CLK
  - 400ns 16 X 16-BIT MULTIPLICATION
  - 800ns 32 / 16-BIT DIVISION
  - ENHANCED BOOLEAN BIT MANIPULATION FACILITIES
  - ADDITIONAL INSTRUCTIONS TO SUPPORT HLL AND OPERATING SYSTEMS
  - SINGLE-CYCLE CONTEXT SWITCHING SUPPORT
- MEMORY ORGANIZATION
  - UP TO 16M BYTE LINEAR ADDRESS SPACE FOR CODE AND DATA (5M BYTE WITH CAN)
  - 2K BYTE ON-CHIP INTERNAL RAM (IRAM)
  - 2K BYTE ON-CHIP EXTENSION RAM (XRAM)
- FAST AND FLEXIBLE BUS
  - PROGRAMMABLE EXTERNAL BUS CHARACTERISTICS FOR DIFFERENT ADDRESS RANGES
  - 8-BIT OR 16-BIT EXTERNAL DATA BUS
  - MULTIPLEXED OR DEMULTIPLEXED EXTERNAL ADDRESS/DATA BUSES
  - FIVE PROGRAMMABLE CHIP-SELECT SIGNALS
  - HOLD-ACKNOWLEDGE BUS ARBITRATION SUPPORT
- INTERRUPT
  - 8-CHANNEL PERIPHERAL EVENT CONTROLLER FOR SINGLE CYCLE, INTERRUPT DRIVEN DATA TRANSFER
  - 16-PRIORITY-LEVEL INTERRUPT SYSTEM WITH 56 SOURCES, SAMPLE-RATE DOWN TO 40ns
- TIMERS
  - TWO MULTI-FUNCTIONAL GENERAL PURPOSE TIMER UNITS WITH 5 TIMERS
  - TWO 16-CHANNEL CAPTURE/COMPARE UNITS
- A/D CONVERTER
  - 16-CHANNEL 10-BIT
  - 7.76µs CONVERSION TIME
- FAIL-SAFE PROTECTION
  - PROGRAMMABLE WATCHDOG TIMER– OSCILLATOR WATCHDOG
- ON-CHIP CAN 2.0B INTERFACE
- ON-CHIP BOOTSTRAP LOADER
- CLOCK GENERATION
  - ON-CHIP PLL
  - DIRECT OR PRESCALED CLOCK INPUT

August 1999

- UP TO 111 GENERAL PURPOSE I/O LINES – INDIVIDUALLY PROGRAMMABLE AS INPUT, OUTPUT OR SPECIAL FUNCTION
- PROGRAMMABLE DRIVE STRENGTH
- PROGRAMMABLE THRESHOLD (HYSTERESIS) IDLE AND POWER DOWN MODES
- IDLE CURRENT <95mA
- POWER-DOWN SUPPLY CURRENT <400μA</li>
- 4-CHANNEL PWM UNIT
- SERIAL CHANNELS
  - SYNCHRONOUS/ASYNC SERIAL CHANNEL
  - HIGH-SPEED SYNCHRONOUS CHANNEL
- DEVELOPMENT SUPPORT
  - C-COMPILERS, MACRO-ASSEMBLER PACKAGES, EMULATORS, EVAL BOARDS, HLL-DEBUGGERS, SIMULATORS, LOGIC ANALYZER DISASSEM-BLERS, PROGRAMMING BOARDS
- 144-PIN PQFP PACKAGE

### **I - INTRODUCTION**

The ST10R167 is a derivative of the STMicroelectronics ST10 family of 16-bit single-chip CMOS microcontrollers. It combines high CPU performance (up to 12.5 million **Figure 1**: Logic Symbol

instructions per second) with high peripheral functionality and enhanced I/O capabilities. It also provides on-chip high-speed RAM and clock generation via PLL.

RD	95	0	External Memory Read Strobe. RD is activated for every external instruc- tion or data read access.			

### II - PIN DATA (continued)

### Table 1 : Pin list (continued)

Symbol	Pin	Туре	Function
WR/WRL	96	0	External Memory Write Strobe. In $\overline{\text{WR}}$ -mode this pin is activated for every external data write access. In $\overline{\text{WRL}}$ -mode this pin is activated for low byte data write accesses on a 16-bit bus, and for every data write access on an 8-bit bus. See WRCFG in register SYSCON for mode selection.
READY/READY	97	I	Ready Input. The active level is programmable. When the Ready function is enabled, the selected inactive level at this pin during an external memory access will force the insertion of memory cycle time waitstates until the pin returns to the selected active level.
ALE	98	0	Address Latch Enable Output. Can be used for latching the address into external memory or an address latch in the multiplexed bus modes.
ĒĀ	99	Ι	External Access Enable pin. A low level at this pin during and after Reset forces the ST10R167 to begin instruction execution out of external memory. A high level forces execution out of the internal Flash Memory.
P0L.0 - P0L.7 P0H.0 P0H.1 - P0H.7	100 - 107 108 111 - 117	I/O	Port 0 consists of the two 8-bit bidirectional I/O ports P0L and P0H. It is bit-wise programmable for input or output via direction bits. For a pin con- figured as input, the output driver is put into high-impedance state. In case of an external bus configuration, Port 0 serves as the address (A) and address/data (AD) bus in multiplexed bus modes and as the data (D) bus in demultiplexed bus modes.
			Demultiplexed bus modes:
			Data Path Width         8-bit         16-bit           P0L.0         - P0L.7         :         D0 - D7         D0 - D7           P0H.0         - P0H.7         :         I/O         D8 - D15
			Multiplexed bus modes:
			Data Path Width : 8-bit 16-bit P0L.0 – P0L.7 : AD0 – AD7 AD0 - AD7 P0H.0 – P0H.7 : A8 - A15 AD8 - AD15
P1L.0 - P1L.7 P1H.0 - P1H.7	118 - 125 128 - 135	I/O	Port 1 consists of the two 8-bit bidirectional I/O ports P1L and P1H. It is bit-wise programmable for input or output via direction bits. For a pin con- figured as input, the output driver is put into high-impedance state. Port 1 is used as the 16-bit address bus (A) in demultiplexed bus modes and also after switching from a demultiplexed bus mode to a multiplexed bus mode. The following PORT1 pins also serve for alternate functions:
	132 133 134 135	   	P1H.4CC24IOCAPCOM2: CC24 Capture InputP1H.5CC25IOCAPCOM2: CC25 Capture InputP1H.6CC26IOCAPCOM2: CC26 Capture InputP1H.7CC27IOCAPCOM2: CC27 Capture Input
XTAL1	138	I	Input to the oscillator amplifier and input to the internal clock generator
XTAL2	137	Ο	Output of the oscillator amplifier circuit.
			To clock the device from an external source, drive XTAL1, while leaving XTAL2 unconnected. Minimum and maximum high/low and rise/fall times specified in the AC Characteristics must be observed.
RSTIN	140	Ι	Reset Input with Schmitt-Trigger characteristics. A low level at this pin for a specified duration while the oscillator is running resets the ST10R167. An internal pullup resistor permits power-on reset using only a capacitor connected to $V_{\rm SS}$ . In bidirectional reset mode (enabled by setting bit BDRSTEN in SYSCON register), the RSTIN line is pulled low for the duration of the internal reset sequence.

### II - PIN DATA (continued)

Table 1 : Pin list (continued)

Symbol	Pin	Туре	Function
RSTOUT	141	0	Internal Reset Indication Output. This pin is set to a low level when the part is executing either a hardware-, a software- or a watchdog-timer reset. RSTOUT remains low until the EINIT (end of initialization) instruction is executed.
NMI	142	Ι	Non-Maskable Interrupt Input. A high to low transition at this pin causes the CPU to vector to the NMI trap routine. If bit PWDCFG = '0' in SYSCON register, when the PWRDN (power down) instruction is executed, the NMI pin must be low in order to force the ST10R167 to go into power down mode. If NMI is high and PWDCFG = '0', when PWRDN is executed, the part will continue to run in normal mode. If not used, pin NMI should be pulled high externally.
V <sub>AREF</sub>	37	-	Reference voltage for the A/D converter.
V <sub>AGND</sub>	38	-	Reference ground for the A/D converter.
RPD	84	-	This pin is used as the timing pin for the return from powerdown circuit and power-up asynchronous reset.
V <sub>DD</sub>	17, 46, 56, 72, 82, 93, 109, 126, 136, 144	-	Digital Supply Voltage: = + 5V during normal operation and idle mode. ≥ + 2.5V during power down mode
V <sub>SS</sub>	18, 45, 55, 71, 83, 94, 110, 127, 139, 143	-	Digital Ground.

#### **III - FUNCTIONAL DESCRIPTION**

The architecture of the ST10R167 combines advantages of both RISC and CISC processors and an advanced peripheral subsystem. The

Figure 3 : Block diagram

block diagram gives an overview of the different on-chip components and the high bandwidth internal bus structure of the ST10R167.

10/63

#### **IV - MEMORY ORGANIZATION**

The memory space of the ST10R167 is configured in a Von-Neumann architecture. Code memory, data memory, registers and I/O ports are organized within the same linear address space of 16M Byte.

The entire memory space can be accessed Bytewise or Wordwise. Particular portions of the on-chip memory have additionally been made directly bit addressable.

**ROM**: 32K Byte of on-chip ROM.

**RAM** : 2K Byte of on-chip internal RAM (dual-port) is provided as a storage for data, system stack, general purpose register banks and code. The register bank can consist of up to 16 wordwide (R0 to R15) and/or Bytewide (RL0, RH0, ..., RL7, RH7) general purpose registers.

**XRAM**: 2K Byte of on-chip extension RAM (single port XRAM) is provided as a storage for data, user stack and code.

The XRAM is connected to the internal XBUS and is accessed like an external memory in 16-bit demultiplexed bus-mode without waitstate or read/write delay (80ns access at 25MHz CPU clock). Byte and Word access is allowed.

The XRAM address range is 00'E000h -00'E7FFh if the XRAM is enabled (XPEN bit 2 of SYSCON register). As the XRAM appears like external memory, it cannot be used for the ST10R167's system stack or register banks. The XRAM is not provided for single bit storage and therefore is not bit addressable. If bit XRAMEN is cleared, then any access in the address range 00'E000h - 00'E7FFh will be directed to external memory interface, using the BUSCONx register corresponding to address matching ADDRSELx register.

**SFR/ESFR**: 1024 Byte (2 \* 512 Byte) of address space is reserved for the special function register areas. SFRs are wordwide registers which are used for controlling and monitoring functions of the different on-chip units.

**CAN** : Address range 00'EF00h - 00'EFFFh is reserved for the CAN Module access. The CAN is enabled by setting XPEN bit 2 of the SYSCON register. Accesses to the CAN Module use demultiplexed addresses and a 16-bit data bus (Byte accesses are possible). Two wait states give an access time of 160ns at 25MHz CPU clock. No tristate waitstate is used.

Note If the CAN module is used, Port 4 can not be programmed to output all 8 segment address lines. Thus, only 4 segment address lines can be used, reducing the external memory space to 5M Byte (1M Byte per CS line).

In order to meet the needs of designs where more memory is required than is provided on chip, up to 16M Byte of external RAM and/or ROM can be connected to the microcontroller.

#### **V - CENTRAL PROCESSING UNIT (CPU)**

The CPU includes a 4-stage instruction pipeline, a 16-bit arithmetic and logic unit (ALU) and dedicated SFRs. Additional hardware has been added for a separate multiply and divide unit, a bit-mask generator and a barrel shifter.

Most of the ST10R167's instructions can be executed in one instruction cycle which requires 80ns at 25MHz CPU clock. For example, shift and rotate instructions are processed in one instruction cycle independent of the number of bits to be shifted. Multiple-cycle instructions have been optimized: branches are carried out in 2 cycles, 16 x 16 bit multiplication in 5 cycles and a 32/16 bit division in 10 cycles.The jump cache reduces the execution time of repeatedly performed jumps in a loop, from 2 cycles to 1 cycle. The CPU uses an actual register context consisting of up to 16 Word wide GPRs physically allocated within the on-chip RAM area. A Context Pointer (CP) register determines the base address of the active register bank to be accessed by the CPU. The number of register banks is only restricted by the available internal RAM space. For easy parameter passing, a register bank may overlap others.

A system stack of up to 1024 Byte is provided as a storage for temporary data. The system stack is allocated in the on-chip RAM area, and it is accessed by the CPU via the stack pointer (SP) register. Two separate SFRs, STKOV and STKUN, are implicitly compared against the stack pointer value upon each stack access for the detection of a stack overflow or underflow.

Figure 4 : CPU Block Diagram

#### **VI - EXTERNAL BUS CONTROLLER**

All of the external memory accesses are performed by the on-chip external bus controller. The EBC can be programmed to single chip mode when no external memory is required, or to one of four different external memory access modes:

- 16-/18-/20-/24-bit addresses and 16-bit data, demultiplexed.
- 16-/18-/20-/24-bit addresses and 16-bit data, multiplexed.
- 16-/18-/20-/24-bit addresses and 8-bit data, multiplexed.
- 16-/18-/20-/24-bit addresses and 8-bit data, demultiplexed.

In demultiplexed bus modes addresses are output on Port1 and data is input/output on Port0 or P0L, respectively. In the multiplexed bus modes both addresses and data use Port0 for input/output.

Timing characteristics of the external bus interface (memory cycle time, memory tri-state time, length of ALE and read/write delay) are programmable giving the choice of a wide range of memories and external peripherals. Up to 4 independent address windows may be defined (using register pairs ADDRSELx / BUSCONx) to access different resources and bus characteristics. These address windows are arranged hierarchically where BUSCON4 overrides BUSCON3 and BUSCON2 overrides BUSCON1. All accesses to locations not covered by these 4 address windows are controlled by BUSCON0. Up to 5 external  $\overline{CS}$  signals (4 windows plus default) can be generated in order to save external glue logic. Access to very slow memories is supported by a 'Ready' function.

A HOLD/HLDA protocol is available for bus arbitration which shares external resources with other bus masters. The bus arbitration is enabled by setting bit HLDEN in register SYSCON. After setting HLDEN once, pins P6.7...P6.5 (BREQ, HLDA, HOLD) are automatically controlled by the EBC. In master mode (default after reset) the HLDA pin is an output. By setting bit DP6.7 to'1' the slave mode is selected where pin HLDA is switched to input. This directly connects the slave controller to another master controller without glue logic.

For applications which require less external memory space, the address space can be restricted to 1M Byte, 256K Byte or to 64K Byte. Port 4 outputs all 8 address lines if an address space of 16M Byte is used, otherwise four, two or no address lines.

Chip select timing can be made programmable. By default (after reset), the CSx lines change half a CPU clock cycle after the rising edge of ALE. With the CSCFG bit set in the SYSCON register the CSx lines change with the rising edge of ALE.

The active level of the READY pin can be set by bit RDYPOL in the BUSCONx registers. When the READY function is enabled for a specific address window, each bus cycle within the window must be terminated with the active level defined by bit RDYPOL in the associated BUSCON register.

**A7/** 

#### VII - INTERRUPT SYSTEM

The interrupt response time for internal program execution is from 200ns to 480ns.

The ST10R167 architecture supports several mechanisms for fast and flexible response to service requests that can be generated from various sources internal or external to the microcontroller. Any of these interrupt requests can be serviced by the Interrupt Controller or by the Peripheral Event Controller (PEC).

In contrast to a standard interrupt service where the current program execution is suspended and a branch to the interrupt vector table is performed, just one cycle is 'stolen' from the current CPU activity to perform a PEC service. A PEC service implies a single Byte or Word data transfer between any two memory locations with an additional increment of either the PEC source or the destination pointer. An individual PEC transfer counter is implicitly decremented for each PEC service except when performing in the continuous transfer mode. When this counter reaches zero, a standard interrupt is performed to the corresponding source related vector location. PEC services are very well suited, for example, for supporting the transmission or reception of blocks of data. The ST10R167 has 8 PEC channels each of which offers such fast interrupt-driven data transfer capabilities.

A interrupt control register which contains an interrupt request flag, an interrupt enable flag and an interrupt priority bitfield is dedicated to each existing interrupt source. Thanks to its related register, each source can be programmed to one of sixteen interrupt priority levels. Once starting to be processed by the CPU, an interrupt service can only be interrupted by a higher prioritized service request. For the standard interrupt processing, each of the possible interrupt sources has a dedicated vector location.

Fast external interrupt inputs are provided to service external interrupts with high precision requirements. These fast interrupt inputs feature programmable edge detection (rising edge, falling edge or both edges).

Software interrupts are supported by means of the 'TRAP' instruction in combination with an individual trap (interrupt) number.

Table 2 shows all the available ST10R167 interrupt sources and the corresponding hardware-related interrupt flags, vectors, vector locations and trap (interrupt) numbers :

Source of Interrupt or PEC Service Request	Request Flag	Enable Flag	Interrupt Vector	Vector Location	Trap Number

#### VII - INTERRUPT SYSTEM (continued)

Hardware traps are exceptions or error conditions that arise during run-time. They cause immediate non-maskable system reaction similar to a standard interrupt service (branching to a dedicated vector table location).

The occurrence of a hardware trap is additionally signified by an individual bit in the trap flag regis-

ter (TFR). Except when another higher prioritized trap service is in progress, a hardware trap will interrupt any actual program execution. In turn, hardware trap services can normally not be interrupted by standard or PEC interrupts.

Table 3 shows all of the possible exceptions or error conditions that can arise during run-time:

#### **VIII - CAPTURE/COMPARE (CAPCOM) UNIT**

The ST10R167 has two 16 channel CAPCOM units. They support generation and control of timing sequences on up to 32 channels with a maximum resolution of 320ns at 25MHz CPU clock. The CAPCOM units are typically used to handle high speed I/O tasks such as pulse and waveform generation, pulse width modulation (PMW), Digital to Analog (D/A) conversion, software timing, or time recording relative to external events.

Four 16-bit timers (T0/T1, T7/T8) with reload registers provide two independent time bases for the capture/compare register array.

The input clock for the timers is programmable to several prescaled values of the internal system clock, or may be derived from an overflow/ underflow of timer T6 in module GPT2. This provides a wide range of variation for the timer period and resolution and allows precise adjustments to application specific requirements. In addition, external count inputs for CAPCOM timers T0 and T7 allow event scheduling for the capture/compare registers relative to external events.

Each of the two capture/compare register arrays contain 16 dual purpose capture/compare registers, each of which may be individually allocated to either CAPCOM timer T0 or T1 (T7 or T8, respectively), and programmed for capture or compare functions. Each register has one associated port pin which serves as an input pin for triggering the capture function, or as an output pin (except for CC24...CC27) to indicate the occurrence of a compare event.

When a capture/compare register has been selected for capture mode, the current contents of the allocated timer will be latched (captured) into the capture/compare register in response to an external event at the port pin which is associated with this register. In addition, a specific interrupt request for this capture/compare register is generated. Either a positive, a negative, or both a positive and a negative external signal transition at the pin can be selected as the triggering event. The contents of all registers which have been selected for one of the five compare modes are continuously compared with the contents of the allocated timers. When a match occurs between the timer value and the value in a capture/ compare register, specific actions will be taken based on the selected compare mode (see Table 4).

The input frequencies  $f_{Tx}$  for Tx are determined as a function of the CPU clocks. The formulas are detailed in the user manual. The timer input frequencies, resolution and periods which result from the selected pre-scaler option in TxI when using a 25MHz CPU clock are listed in the table below. The numbers for the timer periods are based on a reload value of 0000<sub>H</sub>. Note that some numbers may be rounded to 3 significant figures (see Table 5).

Compare Modes	Function
Mode 0	Interrupt-only compare mode ; several compare interrupts per timer period are possible
Mode 1	Pin toggles on each compare match ; several compare events per timer period are possible
Mode 2	Interrupt-only compare mode ; only one compare interrupt per timer period is generated
Mode 3	Pin set '1' on match; pin reset '0' on compare time overflow ; only one compare event per timer period is generated
Double Register Mode	Two registers operate on one pin; pin toggles on each compare match ; several compare events per timer period are possible.

#### **IX - GENERAL PURPOSE TIMER UNIT**

The GPT unit is a flexible multifunctional timer/ counter structure which is used for time related tasks such as event timing and counting, pulse width and duty cycle measurements, pulse generation, or pulse multiplication. The GPT unit contains five 16-bit timers organized into two separate modules GPT1 and GPT2. Each timer in each module may operate independently in several different modes, or may be concatenated with another timer of the same module.

#### IX.1 - GPT1

Each of the three timers T2, T3, T4 of the GPT1 module can be configured individually for one of four basic modes of operation: **timer**, **gated timer**, **counter mode and incremental interface mode**. In timer mode, the input clock for a timer is derived from the CPU clock, divided by a programmable prescaler. In counter mode, the timer is clocked in reference to external events. Pulse width or duty cycle measurement is supported in gated timer mode where the operation of a timer is controlled by the 'gate' level on an external input pin. For these purposes, each timer has one associated port pin (TxIN) which is the gate or the clock input.

The table below lists the timer input frequencies, resolution and periods for each pre-scaler option at 25MHz CPU clock. This also applies to the Gated Timer Mode of T3 and to the auxiliary timers T2 and T4 in Timer and Gated Timer Mode (see Table 6).

The count direction (up/down) for each timer is programmable by software or may additionally be

altered dynamically by an external signal on a port pin (TxEUD).

In Incremental Interface Mode, the GPT1 timers (T2, T3, T4) can be directly connected to the incremental position sensor signals A and B by their respective inputs TxIN and TxEUD. Direction and count signals are internally derived from these two input signals so that the contents of the respective timer Tx corresponds to the sensor position. The third position sensor signal TOP0 can be connected to an interrupt input.

Timer T3 has output toggle latches (TxOTL) which changes state on each timer over-flow/underflow. The state of this latch may be output on port pins (TxOUT) e. g. for time out monitoring of external hardware components, or may be used internally to clock timers T2 and T4 for high resolution measurement of long time periods.

In addition to their basic operating modes, timers T2 and T4 may be configured as reload or capture registers for timer T3. When used as capture or reload registers, timers T2 and T4 are stopped. The contents of timer T3 is captured into T2 or T4 in response to a signal at their associated input pins (TxIN). Timer T3 is reloaded with the contents of T2 or T4 triggered either by an external signal or by a selectable state transition of its toggle latch T3OTL. When both T2 and T4 are configured to alternately reload T3 on opposite state transitions of T3OTL with the low and high times of a PWM signal, this signal can be constantly generated without software intervention.

f <sub>CPU</sub> = 25MHz		Timer Input Selection T2I / T3I / T4I									
	000 <sub>B</sub>	001 <sub>B</sub>	010 <sub>B</sub>	011 <sub>B</sub>	100 <sub>B</sub>	101 <sub>B</sub>	110 <sub>B</sub>	111 <sub>B</sub>

#### IX - GENERAL PURPOSE TIMER UNIT (continued)

Figure 5 : Block diagram of GPT1

### IX.2 - GPT2

The GPT2 module provides precise event control and time measurement. It includes two timers (T5, T6) and a capture/reload register (CAPREL). Both timers can be clocked with an input clock which is derived from the CPU clock via a programmable prescaler or with external signals. The count direction (up/down) for each timer is programmable by software or may additionally be altered dynamically by an external signal on a port pin (TxEUD). Concatenation of the timers is supported via the output toggle latch (T6OTL) of timer T6 which changes its state on each timer overflow/underflow.

The state of this latch may be used to clock timer T5, or it may be output on a port pin (T6OUT). The overflows/underflows of timer T6 can additionally be used to clock the CAPCOM timers T0 or T1, and to cause a reload from the CAPREL register.

The CAPREL register may capture the contents of timer T5 based on an external signal transition on the corresponding port pin (CAPIN), and timer T5 may optionally be cleared after the capture procedure. This allows absolute time differences to be measured or pulse multiplication to be performed without software overhead.

The capture trigger (timer T5 to CAPREL) may also be generated upon transitions of GPT1 timer T3 inputs T3IN and/or T3EUD. This is advantageous when T3 operates in Incremental Interface Mode.

Table 7 lists the timer input frequencies, resolution and periods for each pre-scaler option at 25MHz CPU clock.

This also applies to the Gated Timer Mode of T6 and to the auxiliary timer T5 in Timer and Gated Timer Mode.

### **X - PWM MODULE**

The pulse width modulation module can generate up to four PWM output signals using edge-aligned or centre-aligned PWM. In addition, the PWM module can generate PWM burst signals and single shot outputs. Table 8 shows the PWM frequencies for different resolutions. The level of the output signals is selectable and the PWM module can generate interrupt requests.

Table 8 : PWM unit frequencies and resolution at 25MHz clock

Mode 0	Resolution	8-bit	10-bit	12-bit	14-bit	16-bit

Figure 7 : Block diagram of PWM module

#### **XI - PARALLEL PORTS**

The ST10R167 provides up to 111 I/O lines organized into eight input/output ports and one input port.

All port lines are bit-addressable, and all input/output lines are individually (bit-wise) programmable as input or output via direction registers. The I/O ports are true bidirectional ports which are switched to high impedance state when configured as inputs.

The output drivers of five I/O ports can be configured (pin by pin) for push/pull operation or open-drain operation via control registers. During the internal reset, all port pins are configured as inputs.

The input threshold of Port 2, Port 3, Port 7 and Port 8 is selectable (TTL-or CMOS-like), where the special CMOS-like input threshold reduces noise sensitivity due to the input hysteresis.

The input thresholds are selected with bit of PICON register dedicated to blocks of 8 input pins (2-bit for port2, 2-bit for port3, 1-bit for port7, 1-bit for port8).

All pins of I/O ports also support an alternate programmable function:

- Port0 and Port1 may be used as address and data lines when accessing external memory.
- Port 2, Port 7 and Port 8 are associated with the capture inputs or with the compare outputs of the CAPCOM units and/or with the outputs of the PWM module.
- Port 3 includes the alternate functions of timers, serial interfaces, the optional bus control signal BHE and the system clock output (CLKOUT).
- Port 4 outputs the additional segment address bits A16 to A23 in systems where segmentation is enabled to access more than 64K Byte of memory.
- Port 5 is used as analog input channels of the A/D converter or as timer control signals.
- Port 6 provides optional bus arbitration signals (BREQ, HLDA, HOLD) and chip select signals.

All port lines that are not used for alternate functions may be used as general purpose I/O lines.

### **XII - A/D CONVERTER**

A10-bit A/D converter with 16 multiplexed input channels and a sample and hold circuit is integrated on-chip. The sample time (for loading the capacitors) and the conversion time is programmable and can be adjusted to the external circuitry. Overrun error detection/protection is controlled by the ADDAT register. Either an interrupt request is generated when the result of a previous conversion has not been read from the result register at the time the next conversion is complete, or the next conversion is suspended until the previous result has been read. For applications which require less than 16 analog input channels, the remaining channel inputs can be used as digital input port pins. The AD converter of the ST10F168 supports different conversion modes :

- Single channel single conversion : the analog level of the selected channel is sampled once and converted. The result of the conversion is stored in the ADDAT register.
- Single channel continuous conversion : the analog level of the selected channel is repeatedly sampled and converted. The result of the conversion is stored in the ADDAT register.
- Auto scan single conversion : the analog level of the selected channels are sampled once and converted. After each conversion the result is stored in the ADDAT register. The data can be transfered to the RAM by interrupt software management or using the powerfull Peripheral Event Controller data transfert.
- Auto scan continuous conversion : the analog level of the selected channels are repeatedly sampled and converted. The result of the conversion is stored in the ADDAT register. The data can be transfered to the RAM by interrupt software management or using the powerfull Peripheral Event Controller data transfert.
- Wait for ADDAT read mode : when using continuous modes, in order to avoid to overwrite the result of the current conversion by the next one, the ADWR bit of ADCON control register

Table 9 : ADC sample clock and conversion time

must be activated. Then, until the ADDAT register is read, the new result is stored in a temporary buffer and the conversion is on hold.

- Channel injection mode : when using continuous modes, a selected channel can be converted in between without changing the current operating mode. The 10 bit data of the conversion are stored in ADRES field of ADDAT2. The current continuous mode remains active after the single conversion is completed.

The Table : 9 ADC sample clock and conversion time shows the ADC unit conversion clock, sample clock.

A complete conversion will take  $14t_{CC} + 2 t_{SC} + 4$  TCL. This time includes the conversion it-self, the sampling time and the time required to transfer the digital value to the result register. For example, at 25MHz of CPU clock, minimum complete conversion time is 7.76 $\mu$ s.

The A/D converter provides automatic offset and linearity self calibration. The calibration operation is performed in two ways:

- A full calibration sequence is performed after a reset and lasts 1.6ms minimum (at 25MHz CPU clock). During this time, the ADBSY flag is set to indicate the operation. Normal conversion can be performed during this time. The duration of the calibration sequence is then extended by the time consumed by the conversions.

Note : After a power-on reset, the total unadjusted error (TUE) of the ADC might be worse than  $\pm 2LSB$  (max.  $\pm 4LSB$ ). During the full calibration sequence, the TUE is constantly improved until at the end of the cycle, TUE is within the specified limits of  $\pm 2LSB$ .

 One calibration cycle is performed after each conversion : each calibration cycle takes 4 ADC clock cycles. These operation cycles ensure constant updating of the ADC accuracy, compensating changing operating conditions.

40070	Conversion C	Clock t <sub>CC</sub>	10070	Sample	Clock t <sub>SC</sub>
ADCTC	$TCL^1 = 1/2 \times f_{XTAL}$	At f <sub>CPU</sub> = 25MHz	ADSTC	-	At f <sub>CPU</sub> = 25MHz
00	TCL x 24	0.48µs	00	t <sub>CC</sub>	0.48µs <sup>2</sup>
01	Reserved, do not use	-	01	t <sub>CC</sub> x 2	0.96µs <sup>2</sup>
10	TCL x 96	1.92µs	10	t <sub>CC</sub> x 4	1.92µs <sup>2</sup>
11	TCL x 48	0.96µs	11	t <sub>CC</sub> x 8	3.84µs <sup>2</sup>

Note 1. See chapter XX. 2.  $t_{CC} = TCL \times 24$ .

### **XIII - SERIAL CHANNELS**

Serial communication with other microcontrollers, processors, terminals or external peripheral components is provided by two serial interfaces: the asynchronous/synchronous serial channel (ASC0) and the high-speed synchronous serial channel (SSC).

Two dedicated Baud rate generators set up all standard Baud rates without the requirement of oscillator tuning.

For transmission, reception and erroneous reception, 3 separate interrupt vectors are provided for each serial channel.

#### ASCO

ASCO supports full-duplex asynchronous communication up to 781.25K Baud and half-duplex synchronous communication up to 5M Baud at 25MHz system clock. For asynchronous operation, the Baud rate generator provides a clock with 16 times the rate of the established Baud rate.

The table below lists various commonly used Baud rates together with the required reload values and the deviation errors compared to the intended Baud rate (see Table 10).

For synchronous operation, the Baud rate generator provides a clock with 4 times the rate of the established Baud rate.

SOBR	S = '0', f <sub>CPU</sub> = 25M	Hz	SOBR	S = '1', f <sub>CPU</sub> = 25M	IHz
Baud Rate (Baud)	Deviation Error	Reload Value	Baud Rate (Baud)	Deviation Error	Reload Value
781250	±0.0%	0000 <sub>H</sub>	520833	±0.0%	0000 <sub>H</sub>
56000	+7.3% / -0.4%	000C <sub>H</sub> / 000D <sub>H</sub>	56000	+3.3% / -7.0%	0008H / 0009H

2400	+0.2% / -0.1%	0144 <sub>H</sub> / 0145 <sub>H</sub>	2400	+0.0% / -0.5%	00D8H / 00D9H
1200	+0.0% / -0.1%	028A <sub>H</sub> / 028B <sub>H</sub>	1200	+0.0% / -0.2%	01B1H / 01B2H
600	+0.0% / -0.1%	0515 <sub>H</sub> / 0516 <sub>H</sub>	600	+0.0% / -0.1%	0363H / 0364H
95	+0.4% / 0.4%	1FFF <sub>H</sub> / 1FFF <sub>H</sub>	75	+0.0% / 0.0%	1B1FH / 1B20H
			63	+0.9% / 0.9%	1FFFH / 1FFFH

Table 10 : Commonly used Baud rates by reload value and deviation errors

Note The deviation errors given in the table above are rounded. Using a Baud rate crystal will provide correct Baud rates without deviation errors.

#### XIII - SERIAL CHANNELS (continued)

#### High Speed Synchronous Serial Channel (SSC)

The High-Speed Synchronous Serial Interface SSC provides flexible high-speed serial communication between the ST10R167 and other microcontrollers, microprocessors or external peripherals.

The SSC supports full-duplex and half-duplex synchronous communication; The serial clock signal can be generated by the SSC itself (master mode) or be received from an external master (slave mode). Data width, shift direction, clock polarity and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A 16-bit Baud rate generator provides the SSC with a separate serial clock signal. The serial channel SSC has its own dedicated 16-bit Baud rate generator with 16-bit reload capability, allowing Baud rate generation independent from the timers.

SSCBR is the dual-function Baud Rate Generator/ Reload register. Table 11 lists some possible Baud rates against the required reload values and the resulting bit times for a 25MHz CPU clock.

Table 11 : Synchronous	Baud	rate and	reload	values
------------------------	------	----------	--------	--------

Baud Rate	Bit Time	Reload Value
Reserved use a reload value > 0.		0000 <sub>H</sub>
5M Baud	200ns	0001 <sub>H</sub>
3.3M Baud	303ns	0002 <sub>H</sub>
2.5M Baud	400ns	0004 <sub>H</sub>
2M Baud	500ns	0005 <sub>H</sub>
1M Baud	1μs	000B <sub>H</sub>
100K Baud	10µs	007C <sub>H</sub>
10K Baud	100µs	04E1 <sub>H</sub>
1K Baud	1ms	30D3 <sub>H</sub>
190.7 Baud	5.2ms	FFFF <sub>H</sub>

#### **XIV - CAN MODULE**

The integrated CAN module handles the completely autonomous transmission and reception of CAN frames in accordance with the CAN specification V2.0 part B (active) i.e. the on-chip CAN module can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

The CAN module provides full CAN functionality on up to 15 message objects. Message object 15 can be configured for basic CAN functionality.

Both modes provide separate masks for acceptance filtering, allowing a number of identifiers in full CAN mode to be accepted and disregarding a number of identifiers in basic CAN mode.

All message objects can be updated independent from other objects and are equipped for the maximum message length of 8 Byte.

The bit timing is derived from the XCLK and is programmable up to a data rate of 1M Baud. The CAN module uses two pins to interface to a bus transceiver.

#### **XV - WATCHDOG TIMER**

The Watchdog Timer is a fail-safe mechanism which prevents the microcontroller from malfunctioning for long periods of time. The Watchdog Timer is always enabled after a reset of the chip and can only be disabled in the time interval until the EINIT (end of initialization) instruction has been executed. Therefore, the chip start-up procedure is always monitored. The software must be designed to service the watchdog timer before it overflows. If, due to hardware or software related failures, the software fails to do so, the watchdog timer overflows and generates an internal hardware reset. It pulls the RSTOUT pin low in order to allow external hardware components to be reset.

The Watchdog Timer is 16-bit, clocked with the system clock divided by 2 or 128. The high Byte of the watchdog timer register can be set to a pre-specified reload value (stored in WDTREL). Each time it is serviced by the application software, the high Byte of the watchdog timer is reloaded. *For security, rewrite WDTCON each time before the watchdog timer is serviced* 

Reload value in WDTREI	Prescaler for f <sub>CPU</sub>			
	2 (WDTIN = '0')	128 (WDTIN = '1')		
FF <sub>H</sub>	20.48µs	1.31ms		
00 <sub>H</sub>	5.24ms	336ms		

 Table 12 : Watchdog time range for 25MHz CPU clock

### **XVI - INSTRUCTION SET SUMMARY**

The table below lists the instructions of the ST10R167. The various addressing modes, instruction operation, parameters for conditional

execution of instructions, opcodes and a detailed description of each instruction can be found in the "ST10 Family Programming Manual".

Table 13 : Instruction set summary

Mnemonic	Description	Bytes
ADD(B)	Add Word (Byte) operands	2/4
ADDC(B)	Add Word (Byte) operands with Carry	2/4
SUB(B)	Subtract Word (Byte) operands	2/4
SUBC(B)	Subtract Word (Byte) operands with Carry	2/4
MUL(U)	(Un)Signed multiply direct GPR by direct GPR (16-16-bit)	2
DIV(U)	(Un)Signed divide register MDL by direct GPR (16-/16-bit)	2
DIVL(U)	(Un)Signed long divide register MD by direct GPR (32-/16-bit)	2
CPL(B)	Complement direct Word (Byte) GPR	2
NEG(B)	Negate direct Word (Byte) GPR	2
AND(B)	Bitwise AND, (Word/Byte operands)	2/4
OR(B)	Bitwise OR, (Word/Byte operands)	2/4
XOR(B)	Bitwise XOR, (Word/Byte operands)	2/4
BCLR	Clear direct bit	2
BSET	Set direct bit	2
BMOV(N)	Move (negated) direct bit to direct bit	4
BAND, BOR, BXOR	AND/OR/XOR direct bit with direct bit	4
BCMP	Compare direct bit to direct bit	4
BFLDH/L	Bitwise modify masked high/low byte of bit-addressable direct Word memory with immediate data	4
CMP(B)	Compare Word (Byte) operands	2/4
CMPD1/2	Compare Word data to GPR and decrement GPR by 1/2	2/4
CMPI1/2	Compare Word data to GPR and increment GPR by 1/2	2/4
PRIOR	Determine number of shift cycles to normalize direct Word GPR and store result in direct Word GPR	2
SHL / SHR	Shift left/right direct Word GPR	2
ROL / ROR	Rotate left/right direct Word GPR	2
ASHR	Arithmetic (sign bit) shift right direct Word GPR	2
MOV(B)	Move Word (Byte) data	2/4
MOVBS	Move Byte operand to Word operand with sign extension	2/4
MOVBZ	Move Byte operand to Word operand. with zero extension	2/4
JMPA, JMPI, JMPR	Jump absolute/indirect/relative if condition is met	4
JMPS	Jump absolute to a code segment	4
J(N)B	Jump relative if direct bit is (not) set	4
JBC	Jump relative and clear bit if direct bit is set	4

### XVI - INSTRUCTION SET SUMMARY (continued)

Table 13 : Instruction set summary (continued)

Mnemonic	Description	Bytes
JNBS	Jump relative and set bit if direct bit is not set	4
CALLA, CALLI, CALLR	Call absolute/indirect/relative subroutine if condition is met	4
CALLS	Call absolute subroutine in any code segment	4
PCALL	Push direct Word register onto system stack & call absolute subroutine	4
TRAP	Call interrupt service routine via immediate trap number	2
PUSH, POP	Push/pop direct Word register onto/from system stack	2
SCXT	Push direct Word register onto system stack and update register with Word operand	4
RET	Return from intra-segment subroutine	2
RETS	Return from inter-segment subroutine	2
RETP	Return from intra-segment subroutine and pop direct Word register from system stack	2
RETI	Return from interrupt service subroutine	2
SRST	Software Reset	4
IDLE	Enter Idle Mode	4
PWRDN	Enter Power Down Mode (assumes MII-pin low)	4
SRVWDT	Service Watchdog Timer	4
DISWDT	Disable Watchdog Timer	4
EINIT	Signify End-of-Initialization on RSTOUT-pin	4
ATOMIC	Begin ATOMIC sequence	2
EXTR	Begin EXTended Register sequence	2
EXTP(R)	Begin EXTended Page (and Register) sequence	2/4
EXTS(R)	Begin EXTended Segment (and Register) sequence	2/4
NOP	Null operation	2

### **XVII - SYSTEM RESET**

The internal system reset function is invoked <u>either</u> by asserting a hardware reset signal on pin RSTIN (Hardware Reset Input), by the execution of the SRST instruction (Software Reset) or by an overflow of the watchdog timer. Whenever one of these conditions occurs, the microcontroller is reset into its predefined default state. The following type of reset are implemented on the ST10R167:

#### Asynchronous hardware reset

Asynchronous reset does not require a stabilized clock signal on XTAL1, as it is not internally resynchronized. It immediately resets the microcontroller into its default reset state.

This asynchronous reset is required upon power-up of the chip and may be used during catastrophic situations. The rising edge of the RSTIN pin is internally resynchronized before exiting the reset condition. Therefore, only the entry of this hardware reset is asynchronous.

#### Synchronous hardware reset (warm reset)

A warm synchronous hardware reset is triggered when the reset input signal RSTIN is latched low and RPD (Pin 84) is high. The I/Os are immediately (asynchronously) set in high impedance, RSTOUT is driven low. After negation of RSTIN is detected, a short transition period elapses, during which pending internal hold states are cancelled and any current internal access cycles are completed, external bus cycles are aborted.

Then, the internal reset sequence starts for 1024 TCL (512 CPU clock cycles). During this reset sequence, if bit BDRSTEN was previously set by software (bit 5 in SYSCON register), RSTIN pin is driven low and internal reset signal is asserted to reset the microcontroller in its default state. Note that after all reset sequences, bit BDRSTEN is cleared.

After the reset sequence has been completed, the RSTIN input is sampled. If the reset input signal is

active at that time the internal reset condition is prolonged until RSTIN becomes inactive.

#### Software reset

The reset sequence can be triggered at any time by the protected instruction SRST (software reset). This instruction can be executed deliberately within a program, e.g. to leave bootstrap loader mode, or on a hardware trap that reveals a system failure. As for a synchronous hardware reset, the reset sequence lasts 1024 TCL (512 CPU clock cycles), and drives the RSTIN pin low.

#### Watchdog timer reset

When the watchdog timer is not disabled during the initialization or serviced regularly during program execution it will overflow and trigger the reset sequence.

Unlike hardware and software resets, the watchdog reset completes a running external bus cycle if this bus cycle either does not use  $\overline{READY}$ , or if  $\overline{READY}$  is sampled active (low) after the programmed waitstates.

When READY is sampled inactive (high) after the programmed waitstates the running external bus cycle is aborted. The internal reset sequence is then started. The watchdog reset cannot occur while the ST10R167 is in bootstrap loader mode.

#### **Bidirectional reset**

This feature is enabled by bit 3 of the SYSCON register. The bidirectional reset makes the watchdog timer reset and software reset externally visible. It is active for the duration of an internal reset sequences caused by a watchdog timer reset and software reset.

This means that the bidirectional reset transforms an internal watchdog timer reset or software reset into an external hardware reset with a minimum duration of 1024 TCL. The consequence is that during a watchdog timer reset or software reset, the behavior of the ST10R167 is equal to an external hardware reset.

#### **XVIII - POWER REDUCTION MODES**

Two different power reduction modes with different levels of power reduction can be entered under software control.

In **Idle mode** the CPU is stopped, while the peripherals continue their operation. Idle mode can be terminated by any reset or interrupt request.

In **Power Down mode** both the CPU and the peripherals are stopped. Power Down mode can be configured by software in order to be terminated only by a hardware reset or by an external interrupt source on fast external interrupt pins. There are two different operating Power Down modes:

Protected power down mode: selected by setting bit PWDCFG in the SYSCON register to '0'. This mode can be used in conjunction with an external power failure signal which pulls the NMI pin low when a power failure is imminent. The microcontroller enters the NMI trap routine and saves the internal state into RAM. The trap routine then sets a flag or writes a bit pattern into specific RAM locations, and executes the PWRDN instruction. If the NMI pin is still low at this time, Power Down mode will be entered, if not program execution continues. During power

down the voltage at the  $V_{CC}$  pins can be lowered to 2.5 V and the contents of the internal RAM will still be preserved.

– Interruptible power down mode: this mode is selected by setting bit PWDCFG in the SYSCON register. The CPU and peripheral clocks are frozen, and the oscillator and PLL are stopped. To exit power down mode with an external interrupt, an EXxIN (x = 7...0) pin has to be asserted for at least 40ns. This signal enables the internal oscillator and PLL circuitry, and turns on the weak pull-down. If the Interrupt was enabled before entering power down mode, the device executes the interrupt service routine, and then resumes execution after the PWRDN instruction. If the interrupt was disabled, the device executes the instruction following PWRDN instruction, and the Interrupt Request Flag remains set until it is cleared by software.

All external bus actions are completed before Idle or Power Down mode is entered. However, Idle or Power Down mode is not entered if READY is enabled, but has not been activated during the last bus access.

#### **XIX - SPECIAL FUNCTION REGISTER OVERVIEW**

Table 14 lists all SFRs which are implemented in the ST10R167 in alphabetical order.

Bit-addressable SFRs are marked with the letter "b" in column "Name". SFRs within the Extended SFR-Space (ESFRs) are marked with the letter "E" in column "Physical Address". An SFR can be specified by its individual mnemonic name. Depending on the selected addressing mode, an SFR can be accessed via its physical address (using the Data Page Pointers), or via its short 8-bit address (without using the Data Page Pointers).

Tabl	e 14	: Special	function	registers	listed b	y name
------	------	-----------	----------	-----------	----------	--------

Name	Physical address	8-bit address	Description	Reset value
ADCIC b	FF98h	CCh	A/D Converter End Of Conversion Interrupt Control Register	0000h

Table 14 : Special function registers listed by name (continued)

Notes 1. The value depends on the silicon revision and is described in the chapter XIX.1.

2. The system configuration is selected during reset.

 Bit WDTR indicates a watchdog timer triggered reset.
 The XPnIC Interrupt Control Registers control the interrupt requests from integrated X-Bus peripherals. Nodes where no X-Peripherals are connected may be used to generate software controlled interrupt requests by setting the respective XPnIR bit.

The ST10R167 has four Identification registers, mapped in ESFR space. These registers contain:

- a manufacturer identifier,
- a chip identifier, with its revision,
- a internal memory and size identifier,
- programming voltage description.

#### IDMANUF (F07Eh / 3Fh) ESFR

### Description

IDMANUF : Manufacturer Identifier - 0400h: STmicroelectronics Manufacturer (JTAG worldwide normalisation).

IDCHIP (F07Ch / 3Eh) ESFR

### Description

IDCHIP: Device Identifier - 0A72h for ST10R167.

IDMEM (F07Ah / 3Dh) ESFR

#### Description

IDMEM: 1008h for ST10R167 (Romless MCU).

IDPROG (F078h / 3Ch) ESFR

### Description

IDPROG: 0000h for ST10R167 (Romless MCU).

#### **XX - ELECTRICAL CHARACTERISTICS**

#### XX.1 - Absolute maximum ratings

Symbol	Parameter	Value	Unit
V <sub>SS</sub>	Voltage on $V_{DD}$ pins with respect to ground	-0.5, +6.5	V
V <sub>SS</sub>	Voltage on any pin with respect to ground	-0.3 to V <sub>DD</sub> +0.3	V
	Input current on any pin during overload condition	-10, +10	mA
	Absolute sum of all input currents during overload condition	100	mA
P <sub>tot</sub>	Power Dissipation	1.5	W
T <sub>amb</sub>	Ambient Temperature under bias	-40, +125	°C
T <sub>stg</sub>	Storage Temperature	-65, +150	°C
0			

Note Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. During overload conditions ( $V_{IN}$ > $V_{DD}$  or  $V_{IN}$ < $V_{SS}$ ) the voltage on pins with respect to ground ( $V_{SS}$ ) must not exceed the values defined by the Absolute Maximum Ratings.

#### XX.2 - Parameter interpretation

The parameters listed in the following tables represent the characteristics of the ST10C167 and its demands on the system. Where the ST10C167 logic provides signals with their respective timing characteristics, the symbol "CC"

for Controller Characteristics is included in the "Symbol" column.

Where the external system must provide signals with their respective timing characteristics to the ST10C167, the symbol "SR" for System Requirement is included in the "Symbol" column.

38/63

### XX.3 - DC characteristics

 $V_{DD} = 5V \pm 10\%$ ,  $V_{SS} = 0V$ ,  $f_{CPU} = 25MHz$ , Reset active,  $T_A = -40$  to  $+125^{\circ}C$ , unless otherwise specified. **Table 15 :** DC characteristics

Symbol		Parameter	Test Conditions	Mininmum	Maximum	Unit
VIL	SR	Input low voltage	-	- 0.5	0.2 V <sub>DD</sub> – 0.1	V
V <sub>ILS</sub>	SR	Input low voltage (special threshold)	-	- 0.5	2.0	V
VIH	SR	Input high voltage (all except RSTIN and XTAL1)	-	0.2 V <sub>DD</sub> + 0.9	V <sub>DD</sub> + 0.5	V
V <sub>IH1</sub>	SR	Input high voltage RSTIN	-	0.6 V <sub>DD</sub>	V <sub>DD</sub> + 0.5	V
V <sub>IH2</sub>	SR	Input high voltage XTAL1	-	0.7 V <sub>DD</sub>	V <sub>DD</sub> + 0.5	V

I <sub>PD</sub>		Power-down mode supply current	$V_{DD}$ = 5.5 V <sup>7</sup>	100	400	μA

**57** 

39/63

- Notes 1. This specification is not valid for outputs which are switched to open drain mode. In this case the respective output will float and the voltage results from the external circuitry.
  - 2. The maximum current may be drawn while the respective signal line remains inactive.
  - 3. The minimum current must be drawn in order to drive the respective signal line active.

4. This specification is only valid during Reset, or during Hold- or Adapt-mode. Port 6 pins are only affected if they are used as  $\overline{CSx}$  output and the open drain function is not enabled.

5. Partially tested, guaranteed by design characterization.

6. The supply current is a function of the operating frequency. This dependency is illustrated in the figure below. These parameters are tested at  $V_{DDmax}$  and 20MHz CPU clock with all outputs disconnected and all inputs at  $V_{IL}$  or  $V_{IH}$ .

7. This parameter is tested including leakage currents. All inputs (including pins configured as inputs) at 0V to 0.1V or at  $V_{DD} - 0.1V$  to  $V_{DD}$ ,  $V_{REF} = 0V$ , all outputs (including pins configured as outputs) disconnected.

8. Overload conditions occur if the standard operating conditions are exceeded, i.e. the voltage on any pin exceeds the specified range (i.e.  $V_{OV} > V_{DD}$ +0.5V or  $V_{OV} < V_{SS}$ -0.5V). The absolute sum of input overload currents on all port pins may not exceed **50mA** (see Figure 8).

#### XX.3.1 - A/D converter characteristics

 $V_{DD}$  = 5V  $\pm$  10%,  $V_{SS}$  = 0V,  $T_A$  = -40 to +125 °C 4.0V  $\leq V_{AREF} \leq V_{DD}$  + 0.1V,  $V_{SS}$  - 0.1V  $\leq V_{AGND} \leq V_{SS}$  + 0.2V (see Table 16)

Table 16 : A/D	converter	characteristics
----------------	-----------	-----------------

Symbol		Parameter	Test Conditions	Min.	Max.	Unit
V <sub>AIN</sub>	SR	Analog input voltage range	1	V <sub>AGND</sub>	VAREF	V
t <sub>S</sub>	СС	Sample time	2 4	-	2 t <sub>SC</sub>	
t <sub>C</sub>	сс	Conversion time	3 4	-	14 t <sub>CC</sub> + t <sub>S</sub> + 4TCL	
TUE	СС	Total unadjusted error	5	I	± 2	LSB
R <sub>AREF</sub>	SR	Internal resistance of reference voltage source	t <sub>CC</sub> in [ns] <sup>6</sup> <sup>7</sup>	Ι	t <sub>CC</sub> /165 - 0.25	kΩ
R <sub>ASRC</sub>	SR	Internal resistance of analog source	$t_{ m S}$ in [ns] $^2$ $^7$	-	t <sub>S</sub> / 330 - 0.25	kΩ
C <sub>AIN</sub>	СС	ADC input capacitance	7	_	33	pF
40/63						<b>ATI</b>

Notes 1. V<sub>AIN</sub> may exceed V<sub>AGND</sub> or V<sub>AREF</sub> up to the absolute maximum ratings. However, the conversion result in these cases will be X000<sub>H</sub> or X3FF<sub>H</sub>, respectively.

2. During the sample time the input capacitance  $C_1$  can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within  $t_S$ . After the end of the sample time  $t_S$ , changes of the analog input voltage have no effect on the conversion result. Values for the sample clock  $t_{SC}$  depend on programming and can be taken from the table above.

3. This parameter includes the sample time  $t_S$ , the time for determining the digital result and the time to load the result register with the conversion result. Values for the conversion clock  $t_{CC}$  depend on programming and can be taken from the table above.

4. This parameter is fixed by ADC control logic.

5. TUE is tested at  $V_{AREF}$  = 5.0V,  $V_{AGND}$  = 0V,  $V_{CC}$  = 4.9V. It is guaranteed by design characterization for all other voltages within the defined voltage range. The specified TUE is guaranteed only if an overload condition (see  $I_{OV}$  specification) occurs on maximum of 2 not selected analog input pins and the absolute sum of input overload currents on all analog input pins does not exceed 10mA. During the reset calibration sequence the maximum TUE may be ±4 LSB.

6. During the conversion the ADC's capacitance must be repeatedly charged or discharged. The internal resistance of the reference voltage source must allow the capacitance to reach its respective voltage level within  $t_{CC}$ . The maximum internal resistance results from the programmed conversion timing.

7. Partially tested, guaranteed by design characterization.

Sample time and conversion time of the ST10C167's ADC are programmable. The table below should be used to calculate the above timings.

ADCON.15 14 (ADCTC)	Conversion clock $t_{CC}$	ADCON.13 12 (ADSTC)	Sample clock $t_{SC}$
00	TCL * 24	00	tcc
01	Reserved, do not use	01	t <sub>CC</sub> * 2
10	TCL * 96	10	t <sub>CC</sub> * 4
11	TCL * 48	11	t <sub>CC</sub> * 8

#### XX.4 - AC characteristics

#### Test waveforms

Figure 9 : Input output waveforms

#### Figure 10 : Float waveforms

#### XX.4.1 - Definition of internal timing

The internal operation of the ST10C167 is controlled by the internal CPU clock  $f_{CPU}$ . Both edges of the CPU clock can trigger internal (e.g. pipeline) or external (e.g. bus cycles) operations.

The specification of the external timing (AC Characteristics) therefore depends on the time between two consecutive edges of the CPU clock, called "TCL" periods (see Figure 11).

The CPU clock signal can be generated by different mechanisms. The duration of TCL periods and their variation (and also the derived external timing) depends on the mechanism used

Figure 11 : Generation mechanisms for the CPU clock

to generate  $f_{CPU}$ . This influence must be regarded when calculating the timings for the ST10C167.

The example for PLL operation shown in Figure 11 refers to a PLL factor of 4.

The mechanism used to generate the CPU clock is selected during reset by the logic levels on pins P0.15-13 (P0H.7-5).

#### XX.4.2 - Clock generation modes

Table 18 shows the association of the combinations of these three bits with the respective clock generation mode.

Table 1	7	: CPU	Frequency	Generation
---------	---	-------	-----------	------------

P0.15-13 (P0H.7-5)		3 5)	CPU Frequency f <sub>CPU</sub> = f <sub>XTAL</sub> x F	External Clock Input Range <sup>1</sup>	Notes
1	1	1	F <sub>XTAL</sub> x 4	2.5 to 6.25MHz	Default configuration
1	1	0	F <sub>XTAL</sub> x 3	3.33 to 8.33MHz	
1	0	1	F <sub>XTAL</sub> x 2	5 to 12.5MHz	
1	0	0	F <sub>XTAL</sub> x 5	2 to 5MHz	
0	1	1	F <sub>XTAL</sub> x 1	1 to 25MHz	Direct drive <sup>2</sup>
0	1	0	F <sub>XTAL</sub> x 1.5	6.66 to 16.6MHz	
0	0	1	F <sub>XTAL</sub> / 2	2 to 50MHz	CPU clock via prescaler
0	0	0	F <sub>XTAL</sub> x 2.5	4 to 10MHz	

Notes 1. The external clock input range refers to a CPU clock range of 10...25MHz.

2. The maximum frequency depends on the duty cycle of the external clock signal.

#### XX.4.3 - Prescaler operation

When pins P0.15-13 (P0H.7-5) equal '001' during reset the CPU clock is derived from the internal oscillator (input clock signal) by a 2:1 prescaler.

The frequency of  $f_{CPU}$  is half the frequency of  $f_{XTAL}$  and the high and low time of  $f_{CPU}$  (i.e. the duration of an individual TCL) is defined by the period of the input clock  $f_{XTAL}$ .

The timings listed in the AC Characteristics that refer to TCLs, therefore, can be calculated using the period of  $f_{\text{XTAL}}$  for any TCL.

Note that if the bit OWDDIS in SYSCON register is cleared, the PLL is running on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

#### XX.4.4 - Direct drive

When pins P0.15-13 (P0H.7-5) equal '011' during reset the on-chip phase locked loop is disabled and the CPU clock is directly driven from the internal oscillator with the input clock signal.

The frequency of  $f_{CPU}$  directly follows the frequency of  $f_{XTAL}$  so the high and low time of  $f_{CPU}$  (i.e. the duration of an individual TCL) is defined by the duty cycle of the input clock  $f_{XTAL}$ .

The timings listed below that refer to TCL therefore must be calculated using the minimum TCL that is possible under the respective circumstances. This minimum value can be calculated by the following formula:

For two consecutive TCLs the deviation caused by the duty cycle of  $f_{XTAL}$  is compensated so the duration of 2TCL is always  $1/f_{XTAL}$ . The minimum value TCL<sub>min</sub> therefore has to be used only once for timings that require an odd number of TCLs (1,3,...). Timings that require an even number of TCLs (2,4,...) may use the formula:

 $2TCL = 1/f_{XTAL}$ 

Note The address float timings in Multiplexed bus mode ( $t_{11}$  and  $t_{45}$ ) use the maximum duration of TCL (TCL<sub>max</sub> = 1/f<sub>XTAL</sub> x DC<sub>max</sub>) instead of TCL<sub>min</sub>.

Note that if the bit OWDDIS in SYSCON register is cleared, the PLL is running on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

#### XX.4.5 - Oscillator watchdog (OWD)

When the clock option selected is direct drive or direct drive with prescaler, in order to provide a fail safe mechanism in case of a loss of the external clock, an oscillator watchdog is implemented as an additional functionality of the PLL circuitry. This oscillator watchdog operates as follows :

After a reset, the Oscillator Watchdog is enabled by default. To disable the OWD, the bit OWDDIS (bit 4 of SYSCON register) must be set.

When the OWD is enabled, the PLL is running on its free-running frequency, and increment the Oscillator Watchdog counter. On each transition of XTAL1 pin, the Oscillator Watchdog is cleared. If an external clock failure occurs, then the Oscillator Watchdog counter overflows (after 16 PLL clock cycles).

The CPU clock signal will be switched to the PLL free-running clock signal, and the Oscillator Watchdog Interrupt Request (XP3INT) is flagged. The CPU clock will not switch back to the external clock even if a valid external clock exits on XTAL1 pin. Only a hardware reset can switch the CPU clock source back to direct clock input.

When the OWD is disabled, the CPU clock is always fed from the oscillator input and the PLL is switched off to decrease power supply current.

#### XX.4.6 - Phase locked loop

For all other combinations of pins P0.15-13 (P0H.7-5) during reset the on-chip phase locked loop is enabled and provides the CPU clock (see table above). The PLL multiplies the input frequency by the factor F which is selected via the combination of pins P0.15-13 (i.e.  $f_{CPU} = f_{XTAL} *$ F). With every F'th transition of  $f_{XTAL}$  the PLL circuit synchronizes the CPU clock to the input clock. This synchronization is done smoothly, i.e. the CPU clock frequency does not change abruptly.

Due to this adaptation to the input clock the frequency of  $f_{CPU}$  is constantly adjusted so it is locked to  $f_{XTAL}$ . The slight variation causes a jitter of  $f_{CPU}$  which also effects the duration of individual TCLs.

The timings listed in the AC Characteristics that refer to TCL therefore must be calculated using the minimum TCL that is possible under the respective circumstances.

The real minimum value for TCL depends on the jitter of the PLL. The PLL tunes  $F_{CPU}$  to keep it locked on  $F_{XTAL}$ . The relative deviation of TCL is the maximum when it is referred to one TCL period. It decreases according to the formula and to the Figure 12 given below. For *N* periods of TCL the minimum value is computed using the corresponding deviation  $D_N$ :

$$TCL_{MIN} = TCL_{NOM} \times \left(1 - \frac{\left[D_{N}\right]}{100}\right)$$
$$D_{N} = \pm (4 - N/15)[\%]$$

Figure 12 : Approximated maximum PLL jitter

where N = number of consecutive TCL periods and  $1 \le N \le 40$ . So for a duration of 3 TCL periods (N = 3):

 $D_3 = 4 - 3/15 = 3.8\%$ 

 $3TCL_{min} = 3TCL_{NOM} \times (1 - 3.8/100)$ =  $3TCL_{NOM} \times 0.962$ 

 $3TCL_{min} = (57.72 \text{ ns at } f_{CPU} = 25 \text{MHz})$ 

This is especially important for bus cycles using wait states and for the operation of timers, serial interfaces, etc. For all slower operations and longer periods (e.g. pulse train generation or measurement, lower Baud rates, etc.) the deviation caused by the PLL jitter is negligible.

#### XX.4.7 - Memory cycle variables

The tables below use three variables which are derived from the BUSCONx registers and represent the special characteristics of the programmed memory cycle. The following table describes how these variables are to be computed.

Symbol	Description	Values
t <sub>A</sub>	ALE Extension	TCL * <alectl></alectl>
<sup>t</sup> C	Memory Cycle Time wait states	2TCL * (15 - <mctc>)</mctc>
t <sub>F</sub>	Memory Tristate Time	2TCL * (1 - <mttc>)</mttc>

#### XX.4.8 - External clock drive XTAL1

 $V_{DD} = 5V \pm 10\%$ ,  $V_{SS} = 0V$ ,  $T_A = -40$  to +125 °C unless otherwise specified.

Symbol		Parameter	f <sub>CPU</sub> = f <sub>XTAL</sub>		f <sub>CPU</sub> = f <sub>XTAL</sub> / 2		f <sub>CPU</sub> = f <sub>XTAL</sub> * N N = 1.5/2,/2.5/3/4/5		Unit
			Min.	Max.	Min.	Max.	Min.	Max.	
tosc	SR	Oscillator period	40 <sup>1</sup>	1000	20 <sup>2</sup>	500	40 * N	100 * N	ns
t <sub>1</sub>	SR	High time	18 <sup>3</sup>	-	6 <sup>3</sup>	-	10 <sup>3</sup>	_	ns
t <sub>2</sub>	SR	Low time	18 <sup>3</sup>	-	6 <sup>3</sup>	-	10 <sup>3</sup>	-	ns
t <sub>3</sub>	SR	Rise time	-	10 <sup>3</sup>	-	6 <sup>3</sup>	-	10 <sup>3</sup>	ns
t <sub>4</sub>	SR	Fall time	-	10 <sup>3</sup>	-	6 <sup>3</sup>	-	10 <sup>3</sup>	ns

Notes 1. Theoretical minimum. The real minimum value depends on the duty cycle of the input clock signal. 2. 25MHz is the maximum input frequency when using an external crystal oscillator; however, 50MHz can be applied with an external clock source.

3. The input clock signal must reach the defined levels  $V_{IL}$  and  $V_{IH2}$ .

Figure 13 : External clock drive XTAL1

### XX.4.9 - Multiplexed bus

 $\begin{array}{l} V_{DD}=5V\pm10\%,\,V_{SS}=0V,\,T_{A}=-\underline{40}\,to\,\pm\underline{125^{\circ}C}\\ C_{L}\,(for\,Port0,\,Port1,\,Port\,4,\,ALE,\,RD,\,WR,\,BHE,\,CLKOUT)=100pF,\\ C_{L}\,(for\,Port\,6,\,\overline{CS})=100pF\\ ALE\,cycle\,time=6\,TCL+2t_{A}+t_{C}+t_{F}\,(120ns\,at\,25MHz\,CPU\,clock\,without\,wait\,states) \end{array}$ 

Table 18 : Multiplexed bus characteristics

Table 19 : Demultiplexed bus characteristics (continued)

Notes 1. Guaranteed by design characterization.
2. RW-delay and tA refer to the next following bus cycle.
3. Read data is latched with the same clock edge that triggers the address change and the rising RD edge. Therefore address changes before the end of RD have no impact on read cycles.

### XX - ELECTRICAL CHARACTERISTICS (continued)

Figure 18 : External Memory Cycle: demultiplexed bus, with/without read/write delay, normal ALE

Figure 19 : External Memory Cycle: demultiplexed bus, with/without read/write delay, extended ALE

Figure 20 : External Memory Cycle: demultiplexed bus, with/without read/write delay, normal ALE, read/ write chip select

Figure 21 : External Memory Cycle: demultiplexed bus, with/without read/write delay, extended ALE, read/write chip select

### XX.4.11 - CLKOUT and READY

 $\begin{array}{l} \mathsf{V}_{DD} = \mathsf{5V} \pm \mathsf{10\%}, \, \mathsf{V}_{SS} = \mathsf{0V}, \, \mathsf{T}_{\mathsf{A}} = \underline{\mathsf{-40}} \ \underline{\mathsf{to}} \, \underline{\mathsf{+125}} \\ \mathsf{C}_{\mathsf{L}} \ (\text{for Port0, Port1, Port 4, ALE, } \overline{\mathsf{RD}}, \, \overline{\mathsf{WR}}, \, \overline{\mathsf{BHE}}, \, \mathsf{CLKOUT}) = \mathsf{100pF} \\ \mathsf{C}_{\mathsf{L}} \ (\text{for Port 6, } \overline{\mathsf{CS}}) = \mathsf{100pF} \end{array}$ 

### Table 20 : CLKOUT and READY characteristics

Symbol		Parameter	Max. ( = 2	CPU Clock 25MHz	Variabl 1/2TCL	Unit	
			Min.	Max.	Min.	Max.	
t <sub>29</sub>	СС	CLKOUT cycle time	40	40	2TCL	2TCL	ns
t <sub>30</sub>	СС	CLKOUT high time	14	-	TCL – 6	-	ns
t <sub>31</sub>	СС	CLKOUT low time	10	-	TCL – 10	-	ns
t <sub>32</sub>	СС	CLKOUT rise time	-	4	-	4	ns
t <sub>33</sub>	СС	CLKOUT fall time	-	4	-	4	ns
t <sub>34</sub>	СС	CLKOUT rising edge to ALE falling edge	0 + t <sub>A</sub>	10 + t <sub>A</sub>	0 + t <sub>A</sub>	10 + t <sub>A</sub>	ns
t <sub>35</sub>	SR	Synchronous READY setup time to CLKOUT	14	-	14	-	ns
t <sub>36</sub>	SR	Synchronous READY hold time after CLKOUT	4	-	4	-	ns
t <sub>37</sub>	SR	Asynchronous READY low time	54	-	2TCL + 14	-	ns
t <sub>58</sub>	SR	Asynchronous READY setup time <sup>1</sup>	14	-	14	-	ns
t <sub>59</sub>	SR	Asynchronous READY hold time <sup>1</sup>	4	-	4	-	ns
t <sub>60</sub>	SR	Async. $\overline{READY}$ hold time after $\overline{RD}$ , $\overline{WR}$ high (Demultiplexed Bus) <sup>2</sup>	0	$0 + 2t_A + t_C + t_F^2$	0	TCL - 20 + $2t_{A} + t_{C} + t_{F}^{2}$	ns

Notes 1. These timings are given for test purposes only, in order to assure recognition at a specific clock edge.

2. Demultiplexed bus is the worst case. For multiplexed bus 2TCL are to be added to the maximum values. This adds even more time for deactivating READY.

The  $2t_A$  and  $t_C$  refer to the next following bus cycle,  $t_F$  refers to the current bus cycle.

58/63

**\$7** 

#### Figure 22 : CLKOUT and READY

Notes 1. Cycle as programmed, including MCTC waitstates (Example shows 0 MCTC WS).

2. The leading edge of the respective command depends on RW-delay.

3. READY sampled HIGH at this sampling point generates a READY controlled wait state, READY sampled LOW at this sampling point terminates the currently running bus cycle.

4.  $\overline{READY}$  may be deactivated in response to the trailing (rising) edge of the corresponding command ( $\overline{RD}$  or  $\overline{WR}$ ).

5. If the Asynchronous READY signal does not fulfill the indicated setup and hold times with respect to CLKOUT (e.g. because CLKOUT is not enabled), it must fulfill t 37 in order to be safely synchronized. This is guaranteed, if READY is removed in response to the command (see Note 4)).

6. Multiplexed bus modes have a MUX waitstate added after a bus cycle, and an additional MTTC waitstate may be inserted here. For a multiplexed bus with MTTC waitstate this delay is 2 CLKOUT cycles, for a demultiplexed bus without MTTC waitstate this delay is zero.

7. The next external bus cycle may start here.

#### XX.4.12 - External bus arbitration

 $\begin{array}{l} \mathsf{V}_{DD} = \mathsf{5V} \pm \mathsf{10\%}, \, \mathsf{V}_{SS} = \mathsf{0V}, \, \mathsf{T}_{\mathsf{A}} = \frac{-40}{10} \underbrace{\mathsf{to}}_{\mathsf{H}} + 125 \overset{\circ}{\mathsf{C}} \\ \mathsf{C}_{\mathsf{L}} \, (\text{for Port0}, \, \underbrace{\mathsf{Port1}}_{\mathsf{Port1}}, \, \mathsf{Port4}, \, \mathsf{ALE}, \, \overline{\mathsf{RD}}, \, \overline{\mathsf{WR}}, \, \overline{\mathsf{BHE}}, \, \mathsf{CLKOUT}) = \mathsf{100pF} \\ \mathsf{C}_{\mathsf{L}} \, (\text{for Port 6}, \, \overline{\mathsf{CS}}) = \mathsf{100pF} \end{array}$ 

Table 21 : External	bus arbitration
---------------------	-----------------

Symbol		Parameter	Max. CPU Clock = 25MHz		Variable CPU Clock 1/2TCL = 1 to 25MHz		Unit
			Min.	Max.	Min.	Max.	
t <sub>61</sub>	SR	HOLD input setup time to CLKOUT	20	-	20	-	ns
t <sub>62</sub>	СС	CLKOUT to HLDA hig or BREQ low delay	-	20	-	20	ns
t <sub>63</sub>	СС	CLKOUT to HLDA low or BREQ high delay	-	20	-	20	ns
t <sub>64</sub>	СС	CSx release	_1	20	-	20	ns
t <sub>65</sub>	СС	CSx drive	-4	24	-4	24	ns
t <sub>66</sub>	CC	Other signals release	_1	20	_	20	ns
t <sub>67</sub>	СС	Other signals drive	-4	24	-4	24	ns

Note 1. Guaranteed by design characterization.

Figure 23 : External bus arbitration, releasing the bus

Notes 1. The ST10C167 will complete the currently running bus cycle before granting bus access. 2. This is the first possibility for BREQ to become active.

3. The  $\overline{CS}$  outputs will be resistive high (pullup) after  $t_{64}$ .

60/63

Figure 24 : External bus arbitration, (regaining the bus)

Notes 1. This is the last opportunity for BREQ to trigger the indicated regain-sequence. Even if BREQ is activated earlier, the regain-sequence is initiated by HOLD going high. Please note that HOLD may also be deactivated without the ST10C167 requesting the bus. 2. The next ST10C167 driven bus cycle may start here.
