

FEATURES

- Low input bias current: 50 pA maximum**
- Offset voltage**
 - 1.5 mV maximum for ADA4062-2 B grade
 - 2.5 mV maximum for ADA4062-2 A grade
- Offset voltage drift: 4 $\mu\text{V}/^\circ\text{C}$ typical**
- Slew rate: 3.3 V/ μs typical**
- CMRR: 90 dB typical**
- Low supply current: 165 μA typical**
- High input impedance**
- Unity-gain stable**
- Packaging: SOIC, MSOP**

APPLICATIONS

- Power control and monitoring
- Active filters
- Industrial/process control
- Body probe electronics
- Data acquisition
- Integrators
- Input buffering

GENERAL DESCRIPTION

The ADA4062-2 is a dual JFET-input amplifier with industry-leading performance. It offers lower power, offset voltage, drift and ultralow bias current. The ADA4062-2 B grade features typical low offset voltage of 0.5 mV, offset drift of 4 $\mu\text{V}/^\circ\text{C}$, and bias current of 2 pA. The ADA4062-2 is ideal for various applications, including process control, industrial and instrumentation equipment, active filtering, data conversion, buffering, and power control and monitoring. With a low supply current of 165 μA per amplifier, it is also very well suited for lower power applications. The ADA4062-2 is specified for the extended industrial temperature range of -40°C to $+125^\circ\text{C}$ and is available in lead-free SOIC and MSOP packages.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
Supply Voltage	$\pm 18\text{ V}$
Input Voltage	$\pm V_{SY}$
Differential Input Voltage	$\pm V_{SY}$
Output Short-Circuit Duration to GND	Indefinite
Storage Temperature Range	-65°C to $+150^{\circ}\text{C}$
Operating Temperature Range	-40°C to $+125^{\circ}\text{C}$
Junction Temperature Range	-65°C to $+150^{\circ}\text{C}$
Lead Temperature (Soldering, 60 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages. It was measured using a standard 2-layer board.

Table 4. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
8-Lead SOIC	158	43	$^{\circ}\text{C}/\text{W}$
8-Lead MSOP	210	45	$^{\circ}\text{C}/\text{W}$

POWER SEQUENCING

The op amp supply voltages must be established simultaneously with, or before, any input signals are applied. If this is not possible, the input current must be limited to 10 mA.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

TYPICAL PERFORMANCE CHARACTERISTICS

APPLICATIONS INFORMATION

NOTCH FILTER

A notch filter rejects a specific interfering frequency and can be implemented using a single op amp. Figure 53 shows a 60 Hz notch filter that uses the twin T network with the ADA4062-2 configured as a voltage follower. The ADA4062-2 works as a buffer that provides high input resistance and low output impedance. The low bias current (2 pA typical) and high input resistance (10 TΩ typical) of the ADA4062-2 enable large resistors and small capacitors to be used.

Alternatively, different combinations of resistors and capacitors values can be used to achieve the desired notch frequency. However, the major drawback to this circuit topology is the need to ensure that all the resistors and capacitors be closely matched. If they are not closely matched, the notch frequency offset and drift cause the circuit to attenuate at a frequency other than the ideal notch frequency.

Therefore, to achieve the desired performance, 1% or better component tolerances are usually required. In addition, a notch filter requires an op amp with a bandwidth of at least 100 to 200 times the center frequency. Hence, using the ADA4062-2 with a bandwidth of 1.4 MHz is excellent for a 60 Hz notch filter. Figure 54 shows the gain of the notch filter with respect to frequency. At 60 Hz, the notch filter has about 50 dB attenuation of signal.

$$f_o = \frac{1}{2\pi R_1 C_1}$$

$$R_1 = R_2 = 2R_3$$

$$C_1 = C_2 = \frac{C_3}{2}$$

Figure 53. Notch Filter Circuit

Figure 54. Notch Filter: Gain vs. Frequency

HIGH-SIDE SIGNAL CONDITIONING

There are many applications that require the sensing of signals near the positive rail. The ADA4062-2 can be used in high-side current sensing applications. Figure 55 shows a high-side signal conditioning circuit using the ADA4062-2. The ADA4062-2 has an input common-mode range that includes the positive supply ($-11.5 \text{ V} \leq V_{CM} \leq +15 \text{ V}$). In the circuit, the voltage drop across a low value resistor, such as the 0.1 Ω shown in Figure 55, is amplified by a factor of 5 using the ADA4062-2.

Figure 55. High-Side Signal Conditioning

MICROPOWER INSTRUMENTATION AMPLIFIER

The ADA4062-2 is a dual amplifier and is perfectly suited for applications that require lower supply currents. For supply voltages of ±15 V, the supply current per amplifier is 165 μA typical. The ADA4062-2 also offers a typical low offset voltage drift of 4 μV/°C and a very low bias current of 2 pA, which makes it well suited for instrumentation amplifiers.

Figure 56 shows the classic 2-op-amp instrumentation amplifier with four resistors using the ADA4062-2. The key to high CMRR for this instrumentation amplifier are resistors that are well matched to both the resistive ratio and relative drift. For true difference amplification, matching of the resistor ratio is very important, where $R_3/R_4 = R_1/R_2$. Assuming perfectly matched resistors, the gain of the circuit is $1 + R_2/R_1$, which is approximately 100. Tighter matching of two op amps in one package, as is the case with the ADA4062-2, offers a significant boost in performance over the 3-op-amp configuration. Overall, the circuit only requires about 330 μA of supply current.

Figure 56. Micropower Instrumentation Amplifier

PHASE REVERSAL

Phase reversal occurs in some amplifiers when the input common-mode voltage range is exceeded. When the voltage driving the input to these amplifiers exceeds the maximum input common-mode voltage range, the output of the amplifiers changes polarity.

Most JFET input amplifiers have phase reversal if either input exceeds the input common-mode range.

For the ADA4062-2, the output does not phase reverse if one or both of the inputs exceeds the input voltage range but stays below the positive supply rail and 0.5 V above the negative supply rail. With a supply voltage of ± 15 V, phase reversal occurs when the input voltage is a negative signal greater than -14.5 V. This is due to saturation of the input stage leading to forward biasing of the gate-drain diode. Phase reversal in ADA4062-2 can be prevented by using a Schottky diode to clamp the input terminals to each other. In the simple buffer circuit in Figure 57, D1 protects the op amp against phase reversal and R limits the input current that flows into the op amp.
