

# Very Low Noise, Differential Amplifier and 2.5MHz Lowpass Filter

## FEATURES

- $\pm 0.6\text{dB}$  (Max) Ripple 4th Order Lowpass Filter with 2.5MHz Cutoff
- Programmable Differential Gain via Two External Resistors
- Adjustable Output Common Mode Voltage
- Operates and Specified with 3V, 5V,  $\pm 5\text{V}$  Supplies
- 86dB S/N with 3V Supply and  $1\text{V}_{\text{RMS}}$  Output
- Low Distortion,  $1\text{V}_{\text{RMS}}$ ,  $800\Omega$  Load  
1MHz: 95dBc 2nd, 88dBc 3rd
- Fully Differential Inputs and Outputs
- Compatible with Popular Differential Amplifier Pinouts
- SO-8 and DFN-12 Packages

## APPLICATIONS

- High Speed ADC Antialiasing and DAC Smoothing in Networking or Cellular Basestation Applications
- High Speed Test and Measurement Equipment
- Medical Imaging
- Drop-in Replacement for Differential Amplifiers

## DESCRIPTION

The LT<sup>®</sup>6600-2.5 combines a fully differential amplifier with a 4th order 2.5MHz lowpass filter approximating a Chebyshev frequency response. Most differential amplifiers require many precision external components to tail or gain and bandwidth. In contrast, with the LT6600-2.5, two external resistors program differential gain, and the filter's 2.5MHz cutoff frequency and passband ripple are internally set. The LT6600-2.5 also provides the necessary level shifting to set its output common mode voltage to accommodate the reference voltage requirements of A/Ds.

Using a proprietary internal architecture, the LT6600-2.5 integrates an antialiasing filter and a differential amplifier/driver without compromising distortion or low noise performance. At unity gain the measured in band signal-to-noise ratio is an impressive 86dB. At higher gains the input referred noise decreases so the part can process smaller input differential signals without significantly degrading the output signal-to-noise ratio.

The LT6600-2.5 also features low voltage operation. The differential design provides outstanding performance for a  $4\text{V}_{\text{P-P}}$  signal level while the part operates with a single 3V supply. The LT6600-2.5 is available in SO-8 and DFN-12 packages.

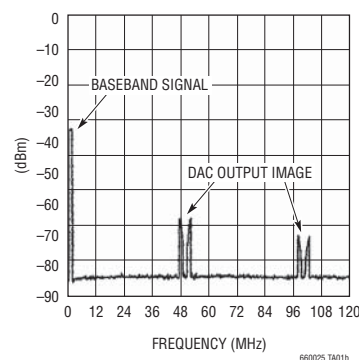

For similar devices with higher cutoff frequency, refer to the LT6600-5, LT6600-10, LT6600-15 and LT6600-20 data sheets.

## ELECTRICAL CHARACTERISTICS

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** This is the temperature coefficient of the internal feedback resistors assuming a temperature independent external resistor ( $R_{IN}$ ).

**Note 3:** The input common mode voltage is the average of the voltages applied to the external resistors ( $R_{IN}$ ). Specification guaranteed for  $R_{IN} \geq 402\Omega$ . For  $\pm 5V$  supplies, the minimum input common mode voltage is guaranteed by design to reach  $-5V$ .

**Note 4:** Distortion is measured differentially using a single-ended stimulus. The input common mode voltage, the voltage at  $V_{OCM}$ , and the voltage at  $V_{MID}$  are equal to one half of the total power supply voltage.

**Note 5:** Output common mode voltage is the average of the voltages at Pins 4 and 5. The output common mode voltage is equal to the voltage applied to Pin 2.

**Note 6:** The LT6600C-2.5 is guaranteed functional over the operating temperature range of  $-40^\circ C$  to  $85^\circ C$ .

**Note 7:** The LT6600C-2.5 is guaranteed to meet specified performance from  $0^\circ C$  to  $70^\circ C$  and is designed, characterized and expected to meet specified performance from  $-40^\circ C$  and  $85^\circ C$ , but is not tested or QA sampled at these temperatures. The LT6600I-2.5 is guaranteed to meet specified performance from  $-40^\circ C$  to  $85^\circ C$ .

**Note 8:** The inputs are protected by back-to-back diodes. If the differential input voltage exceeds  $1.4V$ , the input current should be limited to less than  $10mA$ .

# TYPICAL PERFORMANCE CHARACTERISTICS

# TYPICAL PERFORMANCE CHARACTERISTICS

### Transient Response Gain = 1

## PIN FUNCTIONS (DFN/SO)

**IN<sup>-</sup> and IN<sup>+</sup> (Pins 1, 12/Pins 1, 8):** Input Pins. Signals can be applied to either or both input pins through identical external resistors, R<sub>IN</sub>. The DC gain from differential inputs to the differential outputs is 1580Ω/R<sub>IN</sub>.

**NC (Pins 2, 5, 11/NA):** No Connection

**V<sub>OCM</sub> (Pin 3/Pin 2):** DC Common Mode Reference Voltage for the 2nd Filter Stage. Its value programs the common mode voltage of the differential output of the filter. This is a high impedance input, which can be driven from an external voltage reference, or it can be tied to V<sub>MID</sub> on the PC board. V<sub>OCM</sub> should be bypassed with a 0.01μF ceramic capacitor unless it is connected to a ground plane.

**V<sup>+</sup> and V<sup>-</sup> (Pins 4, 8, 9/Pins 3, 6):** Power Supply Pins. For a single 3.3V or 5V supply (V<sup>-</sup> grounded) a quality 0.1μF ceramic bypass capacitor is required from the positive supply pin (V<sup>+</sup>) to the negative supply pin (V<sup>-</sup>). The bypass

should be as close as possible to the IC. For dual supply applications, bypass V<sup>+</sup> to ground and V<sup>-</sup> to ground with a quality 0.1μF ceramic capacitor.

**OUT<sup>+</sup> and OUT<sup>-</sup> (Pins 6, 7/Pins 4, 5):** Output Pins. These are the filter differential outputs. Each pin can drive a 100Ω and/or 50pF load to AC ground.

**V<sub>MID</sub> (Pin 10/Pin 7):** The V<sub>MID</sub> pin is internally biased at mid-supply, see Block Diagram. For single supply operation, the V<sub>MID</sub> pin should be bypassed with a quality 0.01μF ceramic capacitor to V<sup>-</sup>. For dual supply operation, V<sub>MID</sub> can be bypassed or connected to a high quality DC ground. A ground plane should be used. A poor ground will increase noise and distortion. V<sub>MID</sub> sets the output common mode voltage of the 1st stage of the filter. It has a 5.5kΩ impedance, and it can be overridden with an external low impedance voltage source.

## BLOCK DIAGRAM

## APPLICATIONS INFORMATION

### Interfacing to the LT6600-2.5

Note: The referenced pin numbers correspond to the S8 package. See the Pin Functions for the equivalent DFN-12 package pin numbers.

The LT6600-2.5 requires two equal external resistors,  $R_{IN}$ , to set the differential gain to  $1580\Omega/R_{IN}$ . The inputs to the filter are the voltages  $V_{IN}^+$  and  $V_{IN}^-$  presented to the see external components, Figure 1. The difference between  $V_{IN}^+$  and  $V_{IN}^-$  is the differential input voltage. The average of  $V_{IN}^+$  and  $V_{IN}^-$  is the common mode input voltage. Similarly, the voltages  $V_{OUT}^+$  and  $V_{OUT}^-$  appearing at Pins 4 and 5 of the LT6600-2.5 are the filter outputs. The difference between  $V_{OUT}^+$  and  $V_{OUT}^-$  is the differential output voltage. The average of  $V_{OUT}^+$  and  $V_{OUT}^-$  is the common mode output voltage.

Figure 1 illustrates the LT6600-2.5 operating with a single 3.3V supply and unity passband gain; the input signal is

DC-coupled. The common mode input voltage is 0.5V, and the differential input voltage is  $2V_{P-P}$ . The common mode output voltage is 1.65V, and the differential output voltage is  $2V_{P-P}$  for frequencies below 2.5MHz. The common mode output voltage is determined by the voltage at  $V_{OCM}$ . Since  $V_{OCM}$  is shorted to  $V_{MID}$ , the output common mode is the mid-supply voltage. In addition, the common mode input voltage can be equal to the mid-supply voltage of  $V_{MID}$ .

Figure 2 shows how to AC couple signals into the LT6600-2.5. In this instance, the input is a single-ended signal. AC-coupling allows the processing of single-ended or differential signals with arbitrary common mode levels. The  $0.1\mu F$  coupling capacitor and the  $1580\Omega$  gain setting resistor form a highpass filter, attenuating signals below 1kHz. Larger values of coupling capacitors will proportionally reduce this highpass 3dB frequency.

In Figure 3 the LT6600-2.5 is providing 12dB of gain. The common mode output voltage is set to 2V.

Figure 1. (S8 Pin Numbers)

Figure 2. (S8 Pin Numbers)

Figure 3. (S8 Pin Numbers)

## APPLICATIONS INFORMATION

Use Figure 4 to determine the interface between the LT6600-2.5 and a current output DAC. The gain, or “transimpedance,” is defined as  $A = V_{OUT}/I_{IN}$ . To compute the transimpedance, use the following equation:

$$A = \frac{1580 \cdot R1}{(R1 + R2)} (\Omega)$$

By setting  $R1 + R2 = 1580\Omega$ , the gain equation reduces to  $A = R1(\Omega)$ .

The voltage at the pins of the DAC is determined by  $R1$ ,  $R2$ , the voltage on  $V_{MID}$  and the DAC output current. Consider Figure 4 with  $R1 = 49.9\Omega$  and  $R2 = 1540\Omega$ . The voltage at  $V_{MID}$ , for  $V_S = 3.3V$ , is 1.65V. The voltage at the DAC pins is given by:

$$\begin{aligned} V_{DAC} &= V_{PIN7} \cdot \frac{R1}{R1 + R2 + 1580} + I_{IN} \cdot \frac{R1 \cdot R2}{R1 + R2} \\ &= 26mV + I_{IN} \cdot 48.3\Omega \end{aligned}$$

$I_{IN}$  is  $I_{IN}^+$  or  $I_{IN}^-$ . The transimpedance in this example is  $49.6\Omega$ .

### Evaluating the LT6600-2.5

The low impedance levels and high frequency operation of the LT6600-2.5 require some attention to the matching networks between the LT6600-2.5 and other devices. The previous examples assume an ideal ( $0\Omega$ ) source impedance and a large ( $1k\Omega$ ) load resistance. Among practical examples where impedance must be considered is the evaluation of the LT6600-2.5 with a network analyzer.

Figure 5 is a laboratory setup that can be used to characterize the LT6600-2.5 using single-ended instruments with  $50\Omega$  source impedance and  $50\Omega$  input impedance. For a 12dB gain configuration the LT6600-2.5 requires a  $402\Omega$  source resistance yet the network analyzer output is calibrated for a  $50\Omega$  load resistance. The 1:1 transformer,  $53.6\Omega$  and  $388\Omega$  resistors satisfy the two constraints above. The transformer converts the single-ended source into a differential stimulus. Similarly, the output of the LT6600-2.5 will have lower distortion with larger load resistance yet the analyzer input is typically  $50\Omega$ . The 4:1 turns (16:1 impedance) transformer and the two  $402\Omega$  resistors of Figure 5, present the output of the LT6600-2.5 with a  $1600\Omega$  differential load, or the equivalent of  $800\Omega$  to ground at each output. The impedance seen by the network analyzer input is still  $50\Omega$ , reducing reflections in the cabling between the transformer and analyzer input.

### Differential and Common Mode Voltage Ranges

The rail-to-rail output stage of the LT6600-2.5 can process large differential signal levels. On a 3V supply, the output signal can be  $5.1V_{P-P}$ . Similarly, a 5V supply can support signals as large as  $8.8V_{P-P}$ . To prevent excessive power dissipation in the internal circuitry, the user must limit differential signal levels to  $9V_{P-P}$ .

The two amplifiers inside the LT6600-2.5 have independent control of their output common mode voltage (see the Block Diagram section). The following guidelines will optimize the performance of the filter.

Figure 4. (S8 Pin Numbers)

Figure 5. (S8 Pin Numbers)

## APPLICATIONS INFORMATION

$V_{MID}$  can be allowed to float, but it must be bypassed to an AC ground with a  $0.01\mu\text{F}$  capacitor or some instability may be observed.  $V_{MID}$  can be driven from a low impedance source, provided it remains at least  $1.5\text{V}$  above  $V^-$  and at least  $1.5\text{V}$  below  $V^+$ . An internal resistor divider sets the voltage of  $V_{MID}$ . While the internal  $11\text{k}$  resistors are well matched, their absolute value can vary by  $\pm 20\%$ . This should be taken into consideration when connecting an external resistor network to alter the voltage of  $V_{MID}$ .

$V_{OCM}$  can be shorted to  $V_{MID}$  for simplicity. If a different common mode output voltage is required, connect  $V_{OCM}$  to a voltage source or resistor network. For  $3\text{V}$  and  $3.3\text{V}$  supplies the voltage at  $V_{OCM}$  must be less than or equal to the mid-supply level. For example, voltage ( $V_{OCM}$ )  $\leq 1.65\text{V}$  on a single  $3.3\text{V}$  supply. For power supply voltages higher than  $3.3\text{V}$  the voltage at  $V_{OCM}$  can be set above mid-supply, as shown in Table 1. The voltage on  $V_{OCM}$  should not exceed  $1\text{V}$  below the voltage on  $V_{MID}$ .  $V_{OCM}$  is a high impedance input.

**Table 1. Output Common Range for Various Supplies**

SUPPLY VOLTAGE	DIFFERENTIAL OUT VOLTAGE SWING	OUTPUT COMMON MODE RANGE FOR LOW DISTORTION
3V	4V <sub>p-p</sub>	$1.4\text{V} \leq V_{OCM} \leq 1.6\text{V}$
	2V <sub>p-p</sub>	$1\text{V} \leq V_{OCM} \leq 1.6\text{V}$
	1V <sub>p-p</sub>	$0.75\text{V} \leq V_{OCM} \leq 1.6\text{V}$
5V	8V <sub>p-p</sub>	$2.4\text{V} \leq V_{OCM} \leq 2.6\text{V}$
	4V <sub>p-p</sub>	$1.5\text{V} \leq V_{OCM} \leq 3.5\text{V}$
	2V <sub>p-p</sub>	$1\text{V} \leq V_{OCM} \leq 3.75\text{V}$
$\pm 5\text{V}$	1V <sub>p-p</sub>	$0.75\text{V} \leq V_{OCM} \leq 3.75\text{V}$
	9V <sub>p-p</sub>	$-2\text{V} \leq V_{OCM} \leq 2\text{V}$
	4V <sub>p-p</sub>	$-3.5\text{V} \leq V_{OCM} \leq 3.5\text{V}$
	2V <sub>p-p</sub>	$-3.75\text{V} \leq V_{OCM} \leq 3.75\text{V}$
	1V <sub>p-p</sub>	$-4.25\text{V} \leq V_{OCM} \leq 3.75\text{V}$

NOTE:  $V_{OCM}$  is set by the voltage at this  $R_{IN}$ . The voltage at  $V_{OCM}$  should not exceed  $1\text{V}$  below the voltage at  $V_{MID}$ . To achieve some of the output common mode ranges shown in the table, the voltage at  $V_{MID}$  must be set externally to a value below mid supply.

The LT6600-2.5 was designed to process a variety of input signals including signals centered around the mid-supply voltage and signals that swing between ground and a positive voltage in a single supply system (Figure 1). The range of allowable input common mode voltage (the average of  $V_{IN}^+$  and  $V_{IN}^-$  in Figure 1) is determined by the power supply level and gain setting (see Electrical Characteristics).

### Common Mode DC Currents

In applications like Figure 1 and Figure 3 where the LT6600-2.5 not only provides lowpass filtering but also level shifts the common mode voltage of the input signal, DC currents will be generated through the DC path between input and output terminals. Minimize these currents to decrease power dissipation and distortion.

Consider the application in Figure 3.  $V_{MID}$  sets the output common mode voltage of the 1st differential amplifier inside the LT6600-2.5 (see the Block Diagram section) at  $2.5\text{V}$ . Since the input common mode voltage is near  $0\text{V}$ , there will be approximately a total of  $2.5\text{V}$  drop across the series combination of the internal  $1580\Omega$  feedback resistor and the external  $402\Omega$  input resistor. The resulting  $1.25\text{mA}$  common mode DC current in each input path, must be absorbed by the sources  $V_{IN}^+$  and  $V_{IN}^-$ .  $V_{OCM}$  sets the common mode output voltage of the 2nd differential amplifier inside the LT6600-2.5, and therefore sets the common mode output voltage of the filter. Since, in the example of Figure 3,  $V_{OCM}$  differs from  $V_{MID}$  by  $0.5\text{V}$ , an additional  $625\mu\text{A}$  ( $312\mu\text{A}$  per side) of DC current will flow in the resistors coupling the 1st differential amplifier output stage to filter output. Thus, a total of  $3.125\text{mA}$  is used to translate the common mode voltages.

A simple modification to Figure 3 will reduce the DC common mode currents by  $36\%$ . If  $V_{MID}$  is shorted to  $V_{OCM}$  the common mode output voltage of both op amp stages will be  $2\text{V}$  and the resulting DC current will be  $2\text{mA}$ . Of course, by AC-coupling the inputs of Figure 3, the common mode DC current can be reduced to  $625\mu\text{A}$ .

## APPLICATIONS INFORMATION

### Noise

The noise performance of the LT6600-2.5 can be evaluated with the circuit of Figure 6.

Given the low noise output of the LT6600-2.5 and the 6dB attenuation of the transformer coupling network, it will be necessary to measure the noise floor of the spectrum analyzer and subtract the instrument noise from the filter noise measurement.

Figure 6. (S8 Pin Numbers)

Example: With the IC removed and the 25Ω resistors grounded, Figure 6, measure the total integrated noise ( $e_S$ ) of the spectrum analyzer from 10kHz to 2.5MHz. With the IC inserted, the signal source ( $V_{IN}$ ) disconnected, and the input resistors grounded, measure the total integrated noise out of the filter ( $e_0$ ). With the signal source connected, set the frequency to 100kHz and adjust the amplitude until  $V_{IN}$  measures 100mV<sub>p-p</sub>. Measure the output amplitude,  $V_{OUT}$ , and compute the passband gain  $A = V_{OUT}/V_{IN}$ . Now compute the input referred integrated noise ( $e_{IN}$ ) as:

$$e_{IN} = \frac{\sqrt{(e_0)^2 - (e_S)^2}}{A}$$

Table 2 lists the typical input referred integrated noise for various values of  $R_{IN}$ .

Table 2. Noise Performance

PASSBAND GAIN (V/V)	$R_{IN}$	INPUT REFERRED INTEGRATED NOISE 10kHz TO 2.5MHz	INPUT REFERRED INTEGRATED NOISE 10kHz TO 5MHz
4	402Ω	18μV <sub>RMS</sub>	23μV <sub>RMS</sub>
2	806Ω	29μV <sub>RMS</sub>	39μV <sub>RMS</sub>
1	1580Ω	51μV <sub>RMS</sub>	73μV <sub>RMS</sub>

Figure 7. Input Referred Noise, Gain = 1

Figure 7 is plot of the noise spectral density as a function of frequency for an LT6600-2.5 with  $R_{IN} = 1580\Omega$  using the fixture of Figure 6 (the instrument noise has been subtracted from the results).

The noise at each output is comprised of a differential component and a common mode component. Using a transformer or combiner to convert the differential outputs to single-ended signal rejects the common mode noise and gives a true measure of the S/N achievable in the system. Conversely, if each output is measured individually and the noise power added together, the resulting calculated noise level will be higher than the true differential noise.

### Power Dissipation

The LT6600-2.5 amplifiers combine high speed with large-signal currents in a small package. There is a need to ensure that the die's junction temperature does not exceed 150°C. The LT6600-2.5 S8 package has Pin 6 fused to the lead frame to enhance thermal conduction when connecting to a ground plane or a large metal trace. Metal trace and plated through-holes can be used to spread the heat generated by the device to the backside of the PC board. For example, on a 3/32" FR-4 board with 2oz copper, a total of 660 square millimeters connected to Pin 6 of the LT6600-2.5 S8 (330 square millimeters on each side of the PC board) will result in a thermal resistance,  $\theta_{JA}$ , of about 85°C/W. Without the extra metal trace connected to

## APPLICATIONS INFORMATION

the  $V^-$  pin to provide a heat sink, the thermal resistance will be around 105°C/W. Table 3 can be used as a guide when considering thermal resistance.

**Table 3. LT6600-2.5 SO-8 Package Thermal Resistance**

COPPER AREA		BOARD AREA (mm <sup>2</sup> )	THERMAL RESISTANCE (JUNCTION-TO-AMBIENT)
TOPSIDE (mm <sup>2</sup> )	BACKSIDE (mm <sup>2</sup> )		
1100	1100	2500	65°C/W
330	330	2500	85°C/W
35	35	2500	95°C/W
35	0	2500	100°C/W
0	0	2500	105°C/W

Junction temperature,  $T_J$ , is calculated from the ambient-temperature,  $T_A$ , and power dissipation,  $P_D$ . The power dissipation is the product of supply voltage,  $V_S$ , and supply current,  $I_S$ . Therefore, the junction temperature is given by:

$$T_J = T_A + (P_D \cdot \theta_{JA}) = T_A + (V_S \cdot I_S \cdot \theta_{JA})$$

where the supply current,  $I_S$ , is a function of signal level, load impedance, temperature and common mode voltages.

For a given supply voltage, the worst-case power dissipation occurs when the differential input signal is maximum, the common mode currents are maximum (see Applications Information regarding Common Mode DC Currents), the load impedance is small and the ambient temperature is maximum. To compute the junction temperature, measure the supply current under these worst-case conditions, estimate the thermal resistance from Table 2, then apply the equation for  $T_J$ . For example, using the circuit in Figure 3 with DC differential input voltage of 1V, a differential output voltage of 4V, no load resistance and an ambient temperature of 85°C, the supply current (current into  $V^+$ ) measures 37.6mA. Assuming a PC board layout with a 35mm<sup>2</sup> copper trace, the  $\theta_{JA}$  is 100°C/W. The resulting junction temperature is:

$$T_J = T_A + (P_D \cdot \theta_{JA}) = 85 + (5 \cdot 0.0376 \cdot 100) = 104^\circ\text{C}$$

When using higher supply voltages or when driving small impedances, more copper may be necessary to keep  $T_J$  below 150°C.

# PACKAGE DESCRIPTION

**DF Package**  
**12-Lead Plastic DFN (4mm × 4mm)**  
 (Reference LTC DWG # 05-08-1733 Rev 0)

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS  
 APPLY SOLDER MASK TO AREAS THAT ARE NOT SOLDERED

- NOTE:
1. DRAWING IS PROPOSED TO BE MADE A JEDEC PACKAGE OUTLINE MO-220 VARIATION (WGGD-X)—TO BE APPROVED
  2. DRAWING NOT TO SCALE
  3. ALL DIMENSIONS ARE IN MILLIMETERS
  4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE
  5. EXPOSED PAD SHALL BE SOLDER PLATED
  6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

**PACKAGE DESCRIPTION**

**S8 Package**  
**8-Lead Plastic Small Outline (Narrow .150 Inch)**  
 (Reference LTC DWG # 05-08-1610)

- NOTE:  
 1. DIMENSIONS IN INCHES (MILLIMETERS)  
 2. DRAWING NOT TO SCALE  
 3. THESE DIMENSIONS DO NOT INCLUDE MOLD FLASH OR PROTRUSIONS. MOLD FLASH OR PROTRUSIONS SHALL NOT EXCEED .006" (0.15mm)
