## DESCRIPTION

The 74LV165A is a high-performance, low-power, low-voltage,  $I_s$ -gate CMOS device and superior to most advanced CMOS compatible TTL families.

Schmitt-trigger action at all inputs makes the circuit tolerant for slower input rise and fall times.

This device is fully specified for partial-power-down applications using  $I_{off}$ . The  $I_{off}$  circuitry disables the output, preventing the damaging current back flow through the device when it is powered down.

The 74LV165A is an 8-bit parallel-load or serial-in shift register with complementary serial outputs ( $Q_7$  and  $\overline{Q_7}$ ) available from the last stage. When the parallel-load input ( $\overline{PL}$ ) is LOW, parallel data from the inputs  $D_0$  to  $D_7$  are loaded into the register asynchronously. When input  $\overline{PL}$  is HIGH, data enters the register serially at the input  $DS$  and shifts one place to the right ( $Q_0 \rightarrow Q_1 \rightarrow Q_2$ , etc.) with each positive-going clock transition. This feature allows parallel-to-serial converter expansion by tying the output  $Q_7$  to the input  $DS$  of the succeeding stage.

The clock input is a gate-OR structure which allows one input to be used as an active LOW clock enable input ( $\overline{CE}$ ) input. The pin assignment for the inputs  $CP$  and  $\overline{CE}$  is arbitrary and can be reversed for layout convenience. The LOW-to-HIGH transition of the input  $\overline{CE}$  should only take place while  $CP$  HIGH for predictable operation.

## QUICK REFERENCE DATA

$GND = 0\text{ V}$ ;  $T_{amb} = 25\text{ }^\circ\text{C}$ .

SYMBOL	PARAMETER	CONDITIONS	TYPICAL	UNIT

$C_i$	input capacitance		3.0	pF
$C_{PD}$	power dissipation capacitance per buffer	$V_{CC} = 3.3\text{ V}$ ; notes 1 and 2	24	pF

## Notes

1.  $C_{PD}$  is used to determine the dynamic power dissipation ( $P_D$  in  $\mu\text{W}$ ).

$$P_D = C_{PD} \times V_{CC}^2 \times f_i \times N + \Sigma(C_L \times V_{CC}^2 \times f_o) \text{ where:}$$

$f_i$  = input frequency in MHz;

$f_o$  = output frequency in MHz;

$C_L$  = output load capacitance in pF;

$V_{CC}$  = supply voltage in Volts;

$N$  = total load switching outputs;

$\Sigma(C_L \times V_{CC}^2 \times f_o)$  = sum of the outputs.

2. The condition is  $V_i = GND$  to  $V_{CC}$ .
