

Features

- Built using the advantages and compatibility of CMOS and IXYS HDMOS™ processes
- Latch-Up Protected
- High Peak Output Current: 20A Peak
- Wide Operating Range: 8V to 30V
- Rise And Fall Times of <4ns
- Minimum Pulse Width Of 8ns
- High Capacitive Load Drive Capability: 4nF in <4ns
- Matched Rise And Fall Times
- 32ns Input To Output Delay Time
- Low Output Impedance
- Low Quiescent Supply Currentt

Applications

- Driving RF MOSFETs
- Class D or E Switching Amplifier Drivers
- Multi MHz Switch Mode Power Supplies (SMPS)
- Pulse Generators
- Acoustic Transducer Drivers
- Pulsed Laser Diode Drivers
- DC to DC Converters
- Pulse Transformer Driver

Description

The DEIC420 is a CMOS high speed high current gate driver specifically designed to drive MOSFETs in Class D and E HF RF applications at up to 45MHz, as well as other applications requiring ultrafast rise and fall times or short minimum pulse widths. The DEIC420 can source and sink 20A of peak current while producing voltage rise and fall times of less than 4ns, and minimum pulse widths of 8ns. The input of the driver is compatible with TTL or CMOS and is fully immune to latch up over the entire operating range. Designed with small internal delays, cross conduction/current shoot-through is virtually eliminated in the DEIC420. Its features and wide safety margin in operating voltage and power make the DEIC420 unmatched in performance and value.

The DEIC420 is packaged in DEI's low inductance RF package incorporating DEI's patented ⁽¹⁾ RF layout techniques to minimize stray lead inductances for optimum switching performance. For applications that do not require the power dissipation of the DEIC420, the driver is also available in a 28 pin SOIC package. See the IXDD415SI data sheet for additional information. The DEIC420 is a surface-mount device, and incorporates patented RF layout techniques to minimize stray lead inductances for optimum switching performance.

Lead Description - DEIC420

| SYMBOL | FUNCTION | DESCRIPTION |
|--------|----------------|---|
| VCC | Supply Voltage | Positive power-supply voltage input. These leads provide power to the entire chip. The range for this voltage is from 8V to 30V. |
| IN | Input | Input signal-TTL or CMOS compatible. |
| OUT | Output | Driver Output. For application purposes, this lead is connected, directly to the Gate of a MOSFET |
| GND | Power Ground | The system ground leads. Internally connected to all circuitry, these leads provide ground reference for the entire chip. These leads should be connected to a low noise analog ground plane for optimum performance. |

Note 1: Operating the device beyond parameters with listed “absolute maximum ratings” may cause permanent damage to the device. Typical values indicate conditions for which the device is intended to be functional, but do not guarantee specific performance limits. The guaranteed specifications apply only for the test conditions listed. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

CAUTION: These devices are sensitive to electrostatic discharge; follow proper ESD procedures when handling and assembling this component.

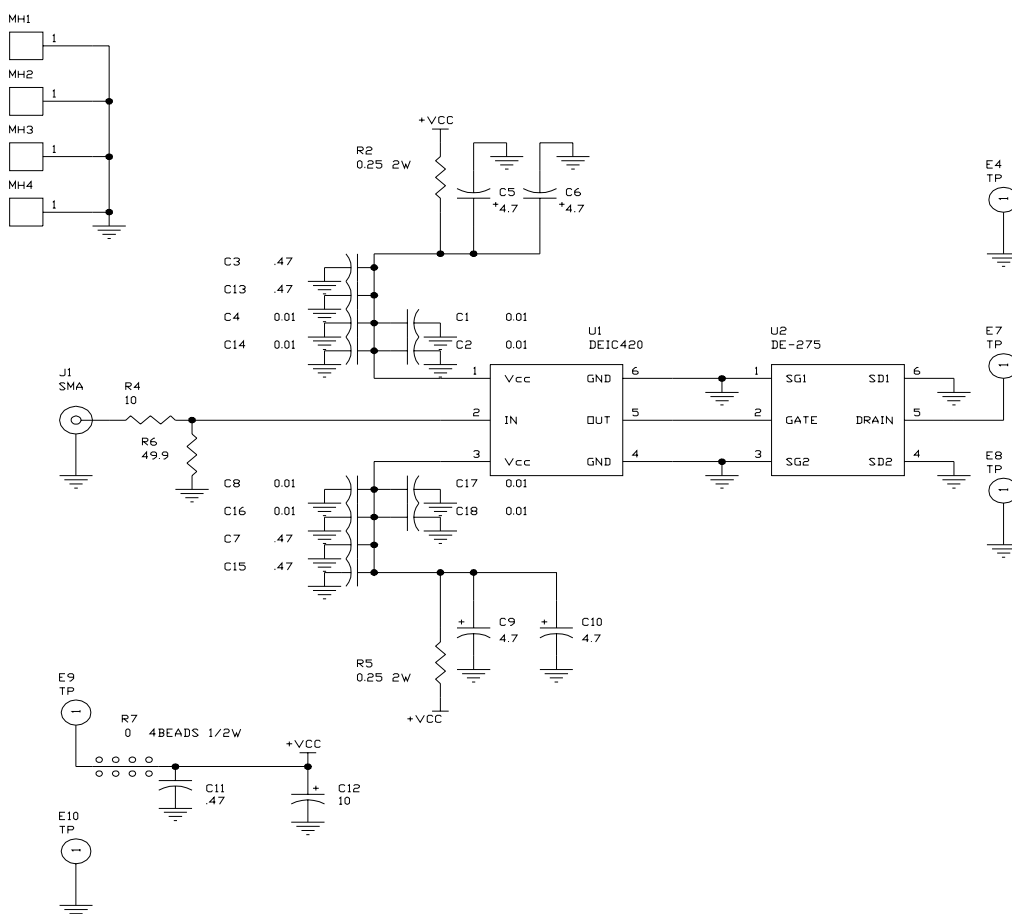

Figure 17 - High Frequency Gate Drive Circuit

APPLICATIONS INFORMATION

High Frequency Gate Drive Circuit

The circuit diagram in figure 17 is a circuit diagram for a very high switching speed, high frequency gate driver circuit using the DEIC420. This is the circuit used in the EVIC420 Evaluation Board, and is capable of driving a MOSFET at up to the maximum operating limits of the DEIC420. The circuit's very high switching speed and high frequency operation dictates the close attention to several important issues with respect to circuit design. The three key elements are circuit loop inductance, Vcc bypassing and grounding.

Circuit Loop Inductance

Referring to Figure 17, the Vcc to Vcc ground current path defines the loop which will generate the inductive term. This loop must be kept as short as possible. The output lead must be no further than 0.375 inches (9.5mm) from the gate of the MOSFET. Furthermore the output ground leads must provide a balanced symmetric coplanar ground return for optimum operation.

Vcc Bypassing

In order for the circuit to turn the MOSFET on properly, the DEIC420 must be able to draw up to 20A of current from the Vcc power supply in 2-6ns (depending upon the input capacitance of the MOSFET being driven). This means that there must be very low impedance between the driver and the power supply. The most common method of achieving this low impedance is to bypass the power supply at the driver with a capacitance value that is at least two orders of magnitude larger than the load capacitance. Usually, this is achieved by placing two or three different types of bypassing capacitors, with complementary impedance curves, very close to the driver itself. (These capacitors should be carefully selected, low inductance, low resistance, high-pulse current-service capacitors). Care should be taken to keep the lengths of the leads between these bypass capacitors and the DEIC420 to an absolute minimum.

The bypassing should be comprised of several values of chip capacitors symmetrically placed on either side of the IC. Recommended values are .01uF, .47uF chips and at least two 4.7uF tantalums.

Grounding

In order for the design to turn the load off properly, the DEIC420 must be able to drain this 20A of current into an adequate grounding system. There are three paths for returning current that need to be considered: Path #1 is between the DEIC420 and its load. Path #2 is between the DEIC420 and its power supply. Path #3 is between

the DEIC420 and whatever logic is driving it. All three of these paths should be as low in resistance and inductance as possible, and thus as short as practical.

Output Lead Inductance

Of equal importance to supply bypassing and grounding are issues related to the output lead inductance. Every effort should be made to keep the leads between the driver and its load as short and wide as possible, and treated as coplanar transmission lines.

In configurations where the optimum configuration of circuit layout and bypassing cannot be used, a series resistance of a few Ohms in the gate lead may be necessary to prevent ringing.

Heat Sinking

For high power operation, the bottom side metalized substrate should be placed in compression against an appropriate heat sink. The substrate is metalized for improved heat dissipation, and is not electrically connected to the device or to ground.

See the DEI technical note "DE-Series MOSFET and IC Mounting Instructions" on the DEI web site at www.directedenergy.com/apptech.htm for detailed mounting instructions. The package dimensions of the DEIC420 are identical to those of the DE-275 MOSFET.
