

- AMR Sensor with $360^{\circ}$ capability
- TDFN outline $2.5 \times 2.5 \times 0.75 \mathrm{~mm}^{3}$
- Three $120^{\circ}$ phase-shifted signals
- Moderate field strength requirements

## DESCRIPTION

The KMT36H is a magnetic field sensor utilizing the anisotropic magneto resistance effect. Therefore the sensor is sensing the magnetic field direction rather than the magnetic field strength. The sensor contains three Wheatstone bridges rotated by $120^{\circ}$. A rotating magnetic field (typical strength $25 \mathrm{kA} / \mathrm{m}$ in the sensor plane) will result in three sinusoidal output signals with a period of $180^{\circ}$, phase shifted by $60^{\circ}$ field angle. By use of a modified atan algorithm the field angle can be calculated with high accuracy.

As an unique feature, the KMT36H is able to measure full $360^{\circ}$ by utilizing an additional magnetic field which is generated by a planar coil that is integrated on the chip. The $180 \% 360^{\circ}$ determination is done by a simple sign distinction and may be computed periodically or only once at power up.

## FEATURES

APPLICATIONS

- Ideal for harsh environments due to magnetic sensing principle
- Contactless absolute angular measurement over $360^{\circ}$
- Accuracy better than +/- $0.5^{\circ}$
- Three bridge signals with $120^{\circ}$ phase difference
- Tiny TDFN-housing $2.5 \times 2.5 \times 0.8 \mathrm{~mm}^{3}$
- Absolute angle measurement
- Potentiometer replacement
- Motor motion control
- Camera positioning
- Robotics

## CHARACTERISTIC VALUES

## SIGNAL EVALUATION

## $180^{\circ}$ EVALUATION

As output voltages $\left(\mathrm{V}_{1}, \mathrm{~V}_{2}, \mathrm{~V}_{3}\right)$ we use the three possible differences between the three signal outputs (see fig. 3). At first the true offsets must be subtracted from the raw signals. The field angle $\alpha$ in a $180^{\circ}$-range then can be calculated in the following manner:

$$
\alpha=\frac{1}{2} \cdot \arctan \left(\frac{2 \cdot \frac{V n}{V m}+1}{\sqrt{3}}\right)
$$

Using the three possible combinations of output signals ( $m, n=1,2 ; 2,3 ; 3,1$ ) three results are obtained, which can be averaged to increase accuracy. Comparing the three results gives additional information about their reliability.

## $360^{\circ}$ EVALUATION

In order to distinguish between $\alpha$ and $\alpha+180^{\circ}$ two additional measurements are needed: one with positive, the other with negative coil current. In the next step the change in the signals due to the influence of the coil current must be calculated. The sign of these coil-induced output voltage changes gives the $360^{\circ}$-information by case differentiation (see figure 4). In principle, this $360^{\circ}$ discrimination needs to be computed only once at start up. Nevertheless, it is recommended to check the measurement periodically.

## APPLICATION EXAMPLE

Figure 5: An exemplary hardware configuration using an Atmel ATtiny44 microcontroller

## ORDERING CODE

| DEVICE | PACKAGE | MOQ | PART NUMBER |
| :---: | :---: | :---: | :---: |
| KMT36H | TDFN $2.5 \times 2.5$ | 1 Reel | G-MRCO-021 |
| KMT36H/SO | SO8 (References: JEDEC MS-012) | 1 Reel | on request |
