

Features

September 2005

- Internal control latches and address decoder
- Short setup and hold times
- Wide operating voltage: 4.5 V to 13.2 V
- 12 Vpp analog signal capability
- R_{ON} 65 Ω max. @ $V_{DD} = 12$ V, 25°C
- $\Delta R_{ON} \leq 10$ Ω @ $V_{DD} = 12$ V, 25C
- Full CMOS switch for low distortion
- Minimum feedthrough and crosstalk
- Low power consumption ISO-CMOS technology
- Internal pull-up resistor for \overline{RESET} pin

Applications

- Key systems
- PBX systems
- Mobile radio
- Test equipment/instrumentation
- Analog/digital multiplexers
- Audio/Video switching

Description

The Zarlink MT8809 is fabricated in Zarlink's ISO-CMOS technology providing low power dissipation and high reliability. The device contains a 8 x 8 array of crosspoint switches along with a 6 to 64 line decoder and latch circuits. Any one of the 64 switches can be addressed by selecting the appropriate six address bits. The selected switch can be turned on or off by applying a logical one or zero to the DATA input. Chip Select (\overline{CS}) allows the crosspoint array to be cascaded for matrix expansion.

Pin Description

Pin #	Name	Description
1	AY2	AY2 Address Line (Input).
2	$\overline{\text{STROBE}}$	STROBE (Input): enables function selected by address and data. Address must be stable before $\overline{\text{STROBE}}$ goes low and DATA must be stable on the rising edge of $\overline{\text{STROBE}}$. Active Low.
3	$\overline{\text{CS}}$	Chip Select (Input): this is used to select the device. Active Low.
4	DATA	DATA (Input): a logic high input will turn on the selected switch and a logic low will turn off the selected switch. Active High.
5	V _{SS}	Ground Reference.
6-9	X0, X2, X4, X6	X0, X2, X4 and X6 Analog (Inputs/Outputs): these are connected to the X0, X2, X4 and X6 rows of the switch array.
10	$\overline{\text{RESET}}$	Master RESET (Input): this is used to turn off all switches regardless of the condition of $\overline{\text{CS}}$. A 100 k Ω internal pull-up resistor is also provided. This can be used in conjunction with a 0.1 μF capacitor (connected to the $\overline{\text{RESET}}$ pin) to perform power-on reset of the device. Active Low.
11-18	Y7 - Y0	Y7 - Y0 Analog (Inputs/Outputs): these are connected to the Y0 - Y7 columns of the switch array.
19	V _{DD}	Positive Power Supply.
20-23	X7, X5, X3, X1	X7, X5, X3 and X1 Analog (Inputs/Outputs): these are connected to the X7, X5, X3 and X1 rows of the switch array.
24-26	AX0-AX2	AX0 - AX2 Address Lines (Inputs).
27, 28	AY0, AY1	AY0 and AY1 Address Lines (Inputs).

Functional Description

The MT8809 is an analog switch matrix with an array size of 8 x 8. The switch array is arranged such that there are 8 columns by 8 rows. The columns are referred to as the Y inputs/outputs and the rows are the X inputs/outputs. The crosspoint analog switch array will interconnect any X I/O with any Y I/O when turned on and provide a high degree of isolation when turned off. The control memory consists of a 64 bit write only RAM in which the bits are selected by the address inputs (AY0-AY2, AX0-AX2). Data is presented to the memory on the DATA input. Data is asynchronously written into memory whenever both the CS (Chip Select) and STROBE inputs are low and are latched on the rising edge of STROBE. A logical "1" written into a memory cell turns the corresponding crosspoint switch on and a logical "0" turns the crosspoint off. Only the crosspoint switches corresponding to the addressed memory location are altered when data is written into memory. The remaining switches retain their previous states. Any combination of X and Y inputs/outputs can be interconnected by establishing appropriate patterns in the control memory. A logical "0" on the RESET input will asynchronously return all memory locations to logical "0" turning off all crosspoint switches regardless of whether CS is high or low.

Address Decode

The six address inputs along with the $\overline{\text{STROBE}}$ and $\overline{\text{CS}}$ (Chip Select) are logically ANDed to form an enable signal for the resettable transparent latches. The DATA input is buffered and is used as the input to all latches. To write to a location, $\overline{\text{RESET}}$ must be high and $\overline{\text{CS}}$ must go low while the address and data are set up. Then the $\overline{\text{STROBE}}$ input is set low and then high causing the data to be latched. The data can be changed while $\overline{\text{STROBE}}$ is low, however, the corresponding switch will turn on and off in accordance with the DATA input. DATA must be stable on the rising edge of $\overline{\text{STROBE}}$ in order for correct data to be written to the latch.
