

## Data Sheet

### Applications

- Low voltage, high density systems with Intermediate Bus Architectures (IBA)
- Point-of-load regulators for high performance DSP, FPGA, ASIC, and microprocessors
- Desktops, servers, and portable computing
- Broadband, networking, optical, and communications systems

### **Benefits**

- Integrates digital power conversion with intelligent power management
- Eliminates the need for external power management components
- Completely programmable via industry-standard I<sup>2</sup>C communication bus
- One part that covers all applications
- Reduces board space, system cost and complexity, and time to market

### Description

Power-One's point-of-load converters are recommended for use with regulated bus converters in an Intermediate Bus Architecture (IBA). The ZY8110 is an intelligent, fully programmable multiphase step-down point-of-load DC-DC module integrating digital power conversion and intelligent power management. When used with ZM7000 Series Digital Power Managers, the ZY8110 completely eliminates the need for external components for sequencing, tracking, protection, monitoring, and reporting. All parameters of the ZY8110 are programmable via the industry-standard I<sup>2</sup>C communication bus and can be changed by a user at any time during product development and service.

### Features

- RoHS lead free and lead-solder-exempt products are available
- Wide input voltage range: 8V–14V
- High continuous output current: 10A
- Programmable output voltage range: 0.5V–5.5V
- Efficiency greater than 92%
- Single-wire serial communication bus for frequency synchronization, programming, and monitoring
- Real time voltage, current, and temperature measurements, monitoring, and reporting
- Optimal voltage positioning with programmable slope
   of the VI line
- Overcurrent, overvoltage, undervoltage, and overtemperature protections with programmable thresholds and types
- Programmable fixed switching frequency 0.5-1.0MHz
- Programmable turn-on and turn-off delays
- Programmable turn-on and turn-off voltage slew rates with tracking protection
- Programmable feedback loop compensation
- Power Good signal with programmable limits
- Programmable fault management
- Start up into the load pre-biased up to 100%
- Current sink capability
- Industry standard size through-hole single-in-line package: 1.2"x0.26"
- Low height of 0.84"
- Wide operating temperature range: 0 to 70°C
- UL60950, CSA C22.2 No. 60950-00, and TUV EN60950-1:2001

Data Sheet

#### 1. **Ordering Information**

| ZY                                    | 81                                      | 10                        | У  | _    | ZZ  |
|---------------------------------------|---|---------------------------|--|------|---|
| Product<br>family:<br>Z-One<br>Module | Series:<br>Intelligent POL<br>Converter | Output<br>Current:<br>10A | <b>RoHS compliance:</b><br><b>No suffix</b> - RoHS compliant<br>with Pb solder exemption <sup>1</sup><br><b>G</b> - RoHS compliant for all<br>six substances | Dash | Packaging Option <sup>2</sup> :<br>R1 –48 pcs Tray<br>Q1 – 1 pc sample for<br>evaluation only |

<sup>1</sup> The solder exemption refers to all the restricted materials except lead in solder. These materials are Cadmium (Cd), Hexavalent chromium (Cr6+), Mercury (Hg), Polybrominated biphenyls (PBB), Polybrominated diphenylethers (PBDE), and Lead (Pb) used anywhere except in solder. <sup>2</sup> Packaging option is used only for ordering and not included in the part number printed on the POL converter label.

<sup>3</sup> Z-One evaluation board is available in only one configuration: ZM7300-KIT-HKS.

Example: ZY8110G-R1: A 48-piece tray of RoHS compliant POL converters. Each POL converter is labeled ZY8110G.

#### **Absolute Maximum Ratings** 2.

Stresses in excess of the absolute maximum ratings may cause performance degradation, adversely affect longterm reliability, and cause permanent damage to the converter.

| Parameter             | Conditions/Description      | Min | Max | Units |

Data Sheet

### 4. Electrical Specifications

Specifications apply at the input voltage from 8V to 14V, output load from 0 to 10A, ambient temperature from 0°C to 70°C, output capacitance consisting of  $3x22\mu$ F low ESR ceramic, and default performance parameters settings unless otherwise noted.

### 4.1 Input Specifications

| Parameter                        | Conditions/Description | Min | Nom | Max | Units |
|----------------------------------|------------------------|-----|-----|-----|-------|
| Input voltage (V <sub>IN</sub> ) |                        | 8   |     | 14  | VDC   |
| Input Current (at no load)       | V <sub>IN</sub> =12V   |     | 31  |     | mADC  |

### 4.2 Output Specifications

| Parameter  | Conditions/Description  | Min              | Nom  | Max   | Units                 |

<sup>&</sup>lt;sup>1</sup> ZY8110 is a step-down converter, thus the output voltage is always lower than the input voltage.

 $<sup>^{2}</sup>$  At the negative output current (bus terminator mode) efficiency of the ZY8110 degrades resulting in increased internal power dissipation. Therefore maximum allowable negative current under specific conditions is 20% lower than the current determined from the derating curves shown in paragraph 5.5.

### 5.4 Transient Response

The pictures below show the deviation of the output voltage in response to the 50-100-50% step load at 2.5A/ $\mu$ s. In all tests the ZY8110 converters operated at switching frequency of 1MHz and had a total 110 $\mu$ F of tantalum and ceramic capacitors connected across the output pins. Bandwidth of the feedback loop was programmed for faster transient response.

### 6. Typical Application

Figure 17. Block Diagram of Typical Application with Digital Power Manager and I<sup>2</sup>C Interface

The schematic of a typical application of ZY8110 point-of-load converters (POL) is shown in Figure 17. The system includes a ZM7300 series Digital Power Manager (DPM), a ZY8110 POL, and may include additional ZY8110 POLs and other Z-One<sup>®</sup> series POLs. All POLs are connected to the DPM and to each other via a single-wire SD (sync/data) line. The line provides synchronization of all POLs to the master clock generated by the DPM and simultaneously performs data transfer between POLs and the DPM. Each POL has a unique 5-bit address programmed by grounding respective address pins. To enable the current share, CS pins of POLs connected in parallel are interconnected.

In addition to the SD line, OK pins of the POLs are connected to the respective OK pins of the DPM. A number of POLs connected to the same OK pin of the DPM forms a group. Grouping of POLs enables users to program, control, and monitor multiple POLs simultaneously and execute advanced fault management schemes.

The type, value, and the number of output capacitors shown in the schematic are required to meet the specifications published in the data sheet. However, ZY8110 POLs are fully operational with different parameters of output capacitors. The feedback loop compensation may need to be adjusted to optimize performance of the POLs for specific parameters of the output capacitors.

### 8. Programmable Features

Performance parameters of ZY8110 POL converters can be programmed via the industry standard I<sup>2</sup>C communication bus without replacing anv Each components or rewiring PCB traces. parameter has a default value stored in the volatile memory registers detailed in Table 1. The setup registers 00h through 14h are programmed at the system power-up. When the user programs new performance parameters, the values in the registers are overwritten. Upon removal of the input voltage, the default values are restored.

ZY8110 converters can be programmed using the Graphical User Interface or directly via the I<sup>2</sup>C bus by using high and low level commands as described in the "DPM Programming Manual".

ZY8110 parameters can be reprogrammed at any time during the system operation and service except for the digital filter coefficients, the switching frequency and the duty cycle limit, that can only be changed when the POL output is turned off.

#### 8.1 Output Voltage

The output voltage can be programmed in the GUI Output Configuration window shown in the Figure 18 or directly via the  $I^2C$  bus by writing into the VOS register shown in Figure 19.

Figure 18. Output Configuration Window

## Data Sheet

### 8.1.1 Output Voltage Setpoint

The output voltage programming range is from 0.5V to 5.5V. To improve the resolution of the output voltage settings, the voltage range is divided into sub-ranges as shown in Table 2.

| Vout min, V | V <sub>out max</sub> , V | Resolution, mV |  |  |
|-------------|--------------------------|----------------|--|--|
| 0.500       | 2.000                    | 12.5           |  |  |
| 2.025       | 5.25                     | 25             |  |  |
| 5.3         | 5.5                      | 50             |  |  |

#### Table 2. Output Voltage Adjustment Resolution

### 8.1.2 Output Voltage Margining

If the output voltage needs to be varied by a certain percentage, the margining function can be utilized. The margining can be programmed in the GUI Output Configuration window or directly via the I<sup>2</sup>C bus using high level commands as described in the "DPM Programming Manual".

In order to properly margin POLs that are connected in parallel, the POLs must be members of one of the Parallel Buses. Refer to the GUI System Configuration Window shown in Figure 44.

### 8.1.3 Optimal Voltage Positioning

Optimal voltage positioning increases the voltage regulation window by properly positioning the output voltage setpoint. Positioning is determined by the load regulation that can be programmed in the GUI Output Configuration window shown in Figure 18 or directly via the  $l^2C$  bus by writing into the CLS register shown in Figure 29.

Figure 20 illustrates optimal voltage positioning concept. If no load regulation is programmed, the headroom (voltage differential between the output voltage setpoint and a regulation limit) is approximately half of the voltage regulation window. When load regulation is programmed, the output voltage will decrease as the output current increases, so the VI characteristic will have a negative slope. Therefore, by properly selecting the operating point, it is possible to increase the headroom as shown in the picture.

Figure 20. Concept of Optimal Voltage Positioning

Increased headroom allows tolerating larger voltage deviations. For example, the step load change from light to heavy load will cause the output voltage to drop. If the optimal voltage positioning is utilized, the output voltage will stay within the regulation window. Otherwise, the output voltage will drop below the lower regulation limit. To compensate for the voltage drop external output capacitance will need to be added, thus increasing cost and complexity of the system.

The effect of optimal voltage positioning is shown in Figure 21 and Figure 22. In this case, switching output load causes large peak-to-peak deviation of the output voltage. By programming load regulation, the peak to peak deviation is dramatically reduced.

Figure 21. Transient Response without Optimal Voltage Positioning

Figure 22. Transient Response with Optimal Voltage Positioning

#### 8.2 Sequencing and Tracking

Turn-on delay, turn-off delay, and rising and falling output voltage slew rates can be programmed in the GUI Sequencing/Tracking window shown in Figure 23 or directly via the  $l^2$ C bus by writing into the DON, DOF, and TC registers, respectively. The registers are shown in Figure 24, Figure 25, and Figure 27.

Figure 23. Sequencing/Tracking Window

### 8.2.1 Turn-On Delay

Turn-on delay is defined as an interval from the application of the Turn-On command until the output voltage starts ramping up.

| R/W-0 R/W-0 R/W-0 R/W-0 R/W-0 R/W-0 R/W-0  |      |      |      |      |      |      |      |  |  |  |  |

|   | <b>Figure</b> | 05 T. |       |       |       |       |       |  |  |  |

Figure 25. Turn-Off Delay Register DOF

Turn-off delay is defined as an interval from the application of the Turn-Off command until the output voltage reaches zero (if the falling slew rate is programmed) or until both high side and low side switches are turned off (if the slew rate is not programmed). Therefore, for the slew rate controlled turn-off the ramp-down time is included in the turn-off delay as shown in Figure 26.

Figure 26. Relationship between Turn-Off Delay and Falling Slew Rate

As it can be seen from the figure, the internally calculated delay  $T_{\rm D}$  is determined by the equation below.

$$T_D = T_{DF} - \frac{V_{OUT}}{dV_F}$$

For proper operation  $T_D$  shall be greater than zero. The appropriate value of the turn-off delay needs to be programmed to satisfy the condition.

Data Sheet

If the falling slew rate control is not utilized, the turnoff delay only determines an interval from the application of the Turn-Off command until both high side and low side switches are turned off. In this case, the output voltage ramp-down process is determined by load parameters.

### 8.2.3 Rising and Falling Slew Rates

The output voltage tracking is accomplished by programming the rising and falling slew rates of the output voltage. To achieve programmed slew rates, the output voltage is being changed in 12.5mV steps where duration of each step determines the slew rate. For example, ramping up a 1.0V output with a slew rate of 0.5V/ms will require 80 steps duration of 25µs each.

Duration of each voltage step is calculated by dividing the master clock frequency generated by the DPM. Since all POLs in the system are synchronized to the master clock, the matching of voltage slew rates of different outputs is very accurate as it can be seen in Figure 6 and Figure 10.

During the turn on process, a POL not only delivers current required by the load ( $I_{LOAD}$ ), but also charges the load capacitance. The charging current can be determined from the equation below:

$$I_{CHG} = C_{LOAD} \times \frac{dV_R}{dt}$$

Where,  $C_{LOAD}$  is load capacitance,  $dV_R/dt$  is rising voltage slew rate, and  $I_{CHG}$  is charging current.

When selecting the rising slew rate, a user needs to ensure that

$$I_{LOAD} + I_{CHG} < I_{OCP}$$

Where  $I_{OCP}$  is the overcurrent protection threshold of the ZY8110. If the condition is not met, then the overcurrent protection will be triggered during the turn-on process. To avoid this,  $dV_R/dt$  and the overcurrent protection threshold should be programmed to meet the condition above.

### 8.3 Protections

ZY8110 Series converters have a comprehensive set of programmable protections. The set includes the output over- and undervoltage protections, overcurrent protection, overtemperature protection, tracking protection, overtemperature warning, and Power Good signal. Status of protections is stored in the ST register shown in Figure 28.

Figure 30. Protection Configuration Register PC2

Note that the overvoltage and undervoltage protection thresholds and Power Good limits are defined as percentages of the output voltage. Therefore, the absolute levels of the thresholds change when the output voltage setpoint is changed either by output voltage adjustment or by margining.

In addition, a user can change type of protections (latching or non-latching) or disable certain protections. These settings are programmed in the GUI Fault Management window shown in Figure 31 or directly via the  $l^2$ C by writing into the PC1 register shown in Figure 32.

Figure 32. Protection Configuration Register PC1

If the non-latching protection is selected, a POL will attempt to restart every 130ms until the condition that triggered the protection is removed. When restarting, the output voltages follow tracking and sequencing settings.

If the latching type is selected, a POL will turn off and stay off. The POL can be turned on after 130ms, if the condition that caused the fault is removed and the respective bit in the ST register was cleared, or the Turn On command was recycled, or the input voltage was recycled.

ZD-01991 Rev. 1.1, 01-Jul-10

### **Data Sheet**

All protections can be classified into three groups based on their effect on system operation: warnings, faults, and errors.

### 8.3.1 Warnings

This group includes Overtemperature Warning and Power Good Signal. The warnings do not turn off POLs but rather generate signals that can be transmitted to a host controller via the  $I^2C$  bus.

### 8.3.1.1 Overtemperature Warning

The Overtemperature Warning is generated when temperature of the controller exceeds 120°C. The Overtemperature Warning changes the PT bit of the status register ST to 0 and sends the signal to the DPM. Reporting is enabled in the GUI Fault Management window or directly via the I<sup>2</sup>C by writing into the PC3 register shown in Figure 34. When the temperature falls below 117°C, the PT bit is cleared and the Overtemperature Warning is removed.

### 8.3.1.2 Power Good

Power Good is an open collector output that is pulled low, if the output voltage is outside of the Power Good window. The window is formed by the Power Good High threshold that is equal to 110% of the output voltage and the Power Good Low threshold that can be programmed at 90 or 95% of the output voltage.

The Power Good protection is only enabled after the output voltage reaches its steady state level. The PGOOD pin is pulled low during transitions of the output voltage from one level to other as shown in Figure 33.

The Power Good Warning pulls the Power Good pin low and changes the PG bit of the status register ST to 0. It sends the signal to the DPM, if the reporting is enabled. When the output voltage returns within the Power Good window, the PG pin is pulled high, the PG bit is cleared and the Power Good Warning is removed. The Power Good pin can also be pulled low by an external circuit to initiate the Power Good Warning.

Note: To retrieve status information, Status Monitoring in the GUI POL Group Configuration Window should be enabled (refer to Digital Power Manager Data Sheet). The DPM will retrieve the status information from each POL on a continuous basis.

### 8.3.2 Faults

This group includes overcurrent, overtemperature, undervoltage, and tracking protections. Triggering any protection in this group will turn off the POL.

### 8.3.2.1 Overcurrent Protection

Overcurrent protection is active whenever the output voltage of the POL exceeds the prebias voltage (if any). When the output current reaches the OC threshold, the output voltage will start decreasing. As soon as the output voltage decreases below the undervoltage protection threshold, the OC fault signal is generated, the POL turns off and the OC bit in the register ST is changed to 0. Both high side and low side switches of the POL are turned off instantly (fast turn-off).

The temperature compensation is added to keep the OC threshold approximately constant at temperatures above room temperature. Note that the temperature compensation can be disabled in the GUI Output Configuration window or directly via the  $I^2C$  by writing into the CLS register. However, it is recommended to keep the temperature compensation enabled.

### 8.3.2.2 Undervoltage Protection

The undervoltage protection is only active during steady state operation of the POL to prevent nuisance tripping. If the output voltage decreases below the UV threshold and there is no OC fault, the UV fault signal is generated, the POL turns off, and the UV bit in the register ST is changed to 0. The output voltage is ramped down according to sequencing and tracking settings (regular turn-off).

### 8.3.2.3 Overtemperature Protection

Overtemperature protection is active whenever the POL is powered up. If temperature of the controller exceeds 120°C, the OT fault is generated, POL turns off, and the OT bit in the register ST is changed to 0. The output voltage is ramped down according to sequencing and tracking settings (regular turn-off).

If non-latching OTP is programmed, the POL will restart as soon as the temperature of the controller decreases below the Overtemperature Warning threshold of 110°C.

ZD-01991 Rev. 1.1, 01-Jul-10

### Data Sheet

### 8.3.2.4 Tracking Protection

Tracking protection is active only when the output voltage is ramping up. The purpose of the protection is to ensure that the voltage differential between multiple rails being tracked does not exceed 250mV. This protection eliminates the need for external clamping diodes between different voltage rails which are frequently recommended by ASIC manufacturers.

When the tracking protection is enabled, the POL continuously compares actual value of the output voltage to its programmed value as defined by the output voltage and its rising slew rate. If absolute

value of the difference exceeds 250mV, the tracking fault signal is generated, the POL turns off, and the TR bit in the register ST is changed to 0. Both high side and low side switches of the POL are turned off instantly (fast turn-off).

The tracking protection can be disabled, if it contradicts requirements of a particular system (for example turning into high capacitive load where rising slew rate is not important). It can be disabled in the GUI Fault Management window or directly via the  $l^2C$  bus by writing into the PC1 register.

Figure 33. Protections Enable Conditions

### 8.3.3 Errors

The group includes overvoltage protection and the phase voltage error. The phase voltage error is not available in ZY8110.

### 8.3.3.1 Overvoltage Protection

The overvoltage protection is active whenever the output voltage of the POL exceeds the pre-bias voltage (if any). If the output voltage exceeds the overvoltage protection threshold, the overvoltage error signal is generated, the POL turns off, and the OV bit in the register ST is changed to 0. The high side switch is turned off instantly, and simultaneously the low side switch is turned on to ensure reliable protection of sensitive loads. The low side switch provides low impedance path to quickly dissipate

energy stored in the output filter and achieve effective voltage limitation.

The OV threshold can be programmed from 110% to 130% of the output voltage setpoint, but not lower than 1.0V.

### 8.3.4 Faults and Errors Propagation

The feature adds flexibility to the fault management scheme by giving users control over propagation of fault signals within and outside of the system. The propagation means that a fault in one POL can be programmed to turn off other POLs and devices in the system, even if they are not directly affected by the fault.

ZD-01991 Rev. 1.1, 01-Jul-10

## Data Sheet

### 8.3.4.1 Grouping of POLs

Z-Series POLs can be arranged in several groups to simplify fault management. A group of POLs is defined as a number of POLs with interconnected OK pins. A group can include from 1 to 32 POLs. If fault propagation within a group is desired, the propagation bit needs to be checked in the GUI Fault Management Window. The parameters can also be programmed directly via the I<sup>2</sup>C bus by writing into the PC3 register shown in Figure 34.

When propagation is enabled, the faulty POL pulls its OK pin low. A low OK line initiates turn-off of other POLs in the group.

| R/W   | -0  | R/W-0  | R/W-1        | R/W-1       | R/W-1   | R/W-1                     | R/W-1 | R/W-1 |  |  |

Figure 34. Protection Configuration Register PC3

In addition, the OK lines can be connected to the DPM to facilitate propagation of faults and errors between groups. One DPM can control up to 4 independent groups. To enable fault propagation between groups, the respective bit needs to be checked in the GUI Fault and Error Propagation window shown in Figure 35.

Figure 35. Fault and Error Propagation Window

In this case low OK line will signal DPM to pull other OK lines low to initiate shutdown of other POLs as programmed in the GUI Fault and Error Propagation window. If an error is propagated, the DPM can also generate commands to turn off a front end (a DC-DC converter generating the intermediate bus voltage) and trigger an optional crowbar protection to accelerate removal of the IBV voltage.

#### 8.3.4.2 Propagation Process

Propagation of a fault (OCP, UVP, OTP, and TRP) initiates regular turn-off of other POLs. The faulty POL in this case performs either the regular or the fast turn-off depending on a specific fault as described in section 8.3.2.

Propagation of an error initiates fast turn-off of other POLs. The faulty POL performs the fast turn-off and turns on its low side switch.

Example of the fault propagation is shown in Figure 36 - Figure 37. In this three-output system (refer to the block diagram in Figure 17), the POL powering the output V3 (Ch 1 in the picture) encounters the undervoltage fault after the turn-on. When the fault propagation is not enabled, the POL turns off and generates the UV fault signal. Because the UV fault triggers the regular turn off, the POL meets its turn-off delay and falling slew rate settings during the turn-ff process as shown in Figure 36. Since the UV fault is programmed to be non-latching, the POL will attempt to restart every 130ms, repeating the process described above until the condition causing the undervoltage is removed.

If the fault propagation between groups is enabled, the POL powering the output V3 pulls its OK line low and the DPM propagates the signal to the POL powering the output V1 that belongs to other group.

ZD-01991 Rev. 1.1, 01-Jul-10

The POL powering the output V1 (Ch3 in the picture) executes the regular turn-off. Since both V1 and V3 have the same delay and slew rate settings they will continue to turn off and on synchronously every 130ms as shown in Figure 37 until the condition causing the undervoltage is removed. The POL powering the output V2 continues to ramp up until it reaches its steady state level.

130ms is the interval from the instant of time when the output voltage ramps down to zero until the output voltage starts to ramp up again. Therefore, the 130ms hiccup interval is guaranteed regardless of the turn-off delay setting.

## **Data Sheet**

#### 8.4 **PWM Parameters**

Z-Series POLs utilize the digital PWM controller. The controller enables users to program most of the PWM performance parameters, such as switching frequency, interleave, duty cycle, and feedback loop compensation.

#### 8.4.1 Switching Frequency

The switching frequency can be programmed in the GUI PWM Controller window shown in Figure 38 or directly via the I<sup>2</sup>C bus by writing into the INT register shown in Figure 39. Note that the content of the register can be changed only when the POL is turned off.

Switching actions of all POLs connected to the SD line are synchronized to the master clock generated by the DPM. Each POL is equipped with a PLL and a frequency divider so they can operate at multiples (including fractional) of the master clock frequency as programmed by a user. The POL converters can operate at 500kHz, 750kHz, and 1MHz. Although synchronized, switching frequencies of different POLs are independent of each other. It is permissible to mix POLs operating at different frequencies in one system. It allows optimizing efficiency and transient response of each POL in the system individually.

Figure 38. PWM Controller Window

Figure 39. Interleave Configuration Register INT

#### 8.4.2 Interleave

Interleave is defined as a phase delay between the synchronizing slope of the master clock on the SD pin and PWM signal of a POL. The interleave can be programmed in the GUI PWM Controller window or directly via the I<sup>2</sup>C bus by writing into the INT register.

Every POL generates switching noise. lf no interleave is programmed, all POLs in the system switch simultaneously and noise reflected to the input source from all POLs is added together as shown in Figure 40.

Figure 40. Input Voltage Noise, No Interleave

ZD-01991 Rev. 1.1, 01-Jul-10

www.power-one.com

Page 22 of 28

Figure 41 shows the input voltage noise of the threeoutput system with programmed interleave. Instead of all three POLs switching at the same time as in the previous example, the POLs V1, V2, and V3 switch at 67.5°, 180°, and 303.75°, respectively. Noise is spread evenly across the switching cycle resulting in more than 1.5 times reduction. To achieve similar noise reduction without the interleave will require the addition of an external LC filter.

ZY8110 interleave is independent of the number of POLs in a system and is fully programmable in 11.25° steps. It allows maximum output noise reduction by intelligently spreading switching energy.

**Note:** Due to noise sensitivity issues that may occur in limited cases, it is recommended to avoid phase lag settings of 112.5 and 123.75 degrees, otherwise false PG and/or OV indications may occur.

#### 8.4.3 Duty Cycle Limit

The ZY8110 is a step-down converter therefore  $V_{OUT}$  is always less than  $V_{IN}$ . The relationship between the two parameters is characterized by the duty cycle and can be estimated from the following equation:

$$DC = \frac{V_{OUT}}{V_{IN.MIN}},$$

Where, DC is the duty cycle,  $V_{OUT}$  is the required maximum output voltage (including margining),  $V_{IN.MIN}$  is the minimum input voltage.

It is good practice to limit the maximum duty cycle of the PWM controller to a somewhat higher value

### **Data Sheet**

compared to the steady-state duty cycle as expressed by the above equation. This will further protect the output from excessive voltages. The duty cycle limit can be programmed in the GUI PWM Controller window or directly via the I<sup>2</sup>C bus by writing into the DCL register shown in Figure 42.

Figure 42. Duty Cycle Limit Register

### 8.4.4 ADC Saturation Feedforward

To speed up the PWM response in case of heavy dynamic loads, the duty cycle can be forced either to 0 or the duty cycle limit depending on the polarity of the transient. This function is equivalent to having two comparators defining a window around the output voltage setpoint. When an error signal is inside the window, it will produce gradual duty cycle change proportional to the error signal. If the error signal goes outside the window (usually due to large output current steps), the duty cycle will change to its limit in one switching cycle. In most cases this will significantly improve transient response of the controller, reducing amount of required external capacitance.

Under certain circumstances, usually when the maximum duty cycle limit significantly exceeds its nominal value, the ADC saturation can lead to the overcompensation of the output error. The phenomenon manifests itself as low frequency oscillations on the output of the POL. It can usually be reduced or eliminated by disabling the ADC saturation or limiting the maximum duty cycle to 120-140% of the calculated value. It is not recommended to use ADC saturation for output voltages higher than 2.0V.

The ADC saturation feedforward can be programmed in the GUI PWM Controller window or

ZD-01991 Rev. 1.1, 01-Jul-10

directly via the I<sup>2</sup>C bus by writing into the DCL register.

#### 8.4.5 Feedback Loop Compensation

Feedback loop compensation can be programmed in the GUI PWM Controller window by setting frequency of poles and zeros of the transfer function.

The transfer function of the POL converter is shown in Figure 43. It is a third order function with two zeros and three poles. Pole 1 is the integrator pole, Pole 2 is used in conjunction with Zero 1 and Zero 2 to adjust the phase lead and limit the gain increase in mid band. Pole 3 is used as a high frequency lowpass filter to limit PWM noise.

Positions of poles and zeroes are determined by coefficients of the digital filter. The filter is characterized by four numerator coefficients ( $C_0$ ,  $C_1$ ,  $C_2$ ,  $C_3$ ) and three denominator coefficients ( $B_1$ ,  $B_2$ ,  $B_3$ ). The coefficients are automatically calculated when desired frequency of poles and zeros is entered in the GUI PWM Controller window. The

### **Data Sheet**

coefficients are stored in the C0H, C0L, C1H, C1L, C2H, C2L, C3H, C3L, B1, B2, and B3 registers.

**Note:** The GUI automatically transforms zero and pole frequencies into the digital filter coefficients. It is strongly recommended to use the GUI to determine the filter coefficients.

Programming feedback loop compensation allows optimizing POL performance for various application conditions. For example, increase in bandwidth can significantly improve dynamic response.

### 8.5 Performance Parameters Monitoring

The POL converters can monitor their own performance parameters such as output voltage, output current, and temperature.

The output voltage is measured at the output sense pins, output current is measured using the ESR of the output inductor and temperature is measured by the thermal sensor built into the controller IC. Output current readings are adjusted based on temperature readings to compensate for the change of ESR of the inductor with temperature.

An 8-Bit Analog to Digital Converter (ADC) converts the output voltage, output current, and temperature into a digital signal to be transmitted via the serial interface. The ADC allows a minimum sampling frequency of 700 Hz for all three values.

Monitored parameters are stored in registers (VOM, IOM, and TMON) that are continuously updated. If the Retrieve Monitoring bits in the GUI Group Configuration window shown in Figure 45 are checked, those registers are being copied into the ring buffer located in the DPM. Contents of the ring buffer can be displayed in the GUI IBS Monitoring Window shown in Figure 46 or it can be read directly via the I<sup>2</sup>C bus using high and low level commands as described in the "DPM Programming Manual".

### 9. Safety

The ZY8110 POL converters do not provide isolation from input to output. The input devices powering ZY8110 must provide relevant isolation requirements according to all IEC60950 based standards. Nevertheless, if the system using the converter needs to receive safety agency approval, certain rules must be followed in the design of the system. In particular, all of the creepage and clearance requirements of the end-use safety requirements must be observed. These requirements are included in UL60950 - CSA60950-00 and EN60950, although specific applications may have other or additional requirements.

The ZY8110 POL converters have no internal fuse. If required, the external fuse needs to be provided to protect the converter from catastrophic failure. Refer to the "Input Fuse Selection for DC/DC converters" application note on <u>www.power-one.com</u> for proper selection of the input fuse. Both input traces and the chassis ground trace (if applicable) must be capable of conducting a current of 1.5 times the value of the fuse without opening. The fuse must not be placed in the grounded input line.

Abnormal and component failure tests were conducted with the POL converter's input protected by a fast-acting 125V, 10A, fuse. If a fuse rated

### Data Sheet

greater than 10A is used, additional testing may be required.

In order for the output of the ZY8110 POL converter to be considered as SELV (Safety Extra Low

Voltage), according to all IEC60950 based standards, the input to the POL needs to be supplied by an isolated secondary source providing a SELV also.

#### Notes:

- 1. NUCLEAR AND MEDICAL APPLICATIONS Power-One products are not designed, intended for use in, or authorized for use as critical components in life support systems, equipment used in hazardous environments, or nuclear control systems without the express written consent of the respective divisional president of Power-One, Inc.
- 2. TECHNICAL REVISIONS The appearance of products, including safety agency certifications pictured on labels, may change depending on the date manufactured. Specifications are subject to change without notice.
