

LMC555 CMOS Timer General Description

The LMC555 is a CMOS version of the industry standard 555 series general purpose timers. In addition to the standard package (SOIC, MSOP, and MDIP) the LMC555 is also available in a chip sized package (8 Bump micro SMD) using National's micro SMD package technology. The LMC555 offers the same capability of generating accurate time delays and frequencies as the LM555 but with much lower power dissipation and supply current spikes. When operated as a one-shot, the time delay is precisely controlled by a single external resistor and capacitor. In the stable mode the oscillation frequency and duty cycle are accurately set by two external resistors and one capacitor. The use of National Semiconductor's LMCMOS[™] process extends both the frequency range and low supply capability.

Features

- Less than 1 mW typical power dissipation at 5V supply
- 3 MHz astable frequency capability
- 1.5V supply operating voltage guaranteed
- Output fully compatible with TTL and CMOS logic at 5V supply
- Tested to -10 mA, +50 mA output current levels
- Reduced supply current spikes during output transitions
- Extremely low reset, trigger, and threshold currents
- Excellent temperature stability
- Pin-for-pin compatible with 555 series of timers
- Available in 8-pin MSOP Package and 8-Bump micro SMD package

		from Trigger to Output		100		ns

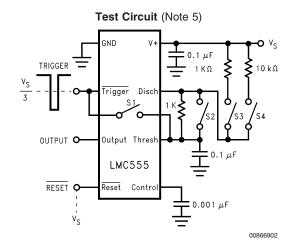

Note 1: All voltages are measured with respect to the ground pin, unless otherwise specified.

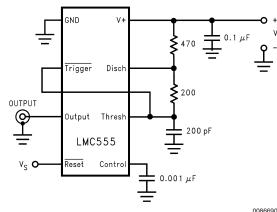

Note 2: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. Electrical Characteristics state DC and AC electrical specifications under particular test conditions which guarantee specific performance limits. This assumes that the device is within the Operating Ratings. Specifications are not guaranteed for parameters where no limit is given, however, the typical value is a good indication of device performance.

Note 3: See AN-450 for other methods of soldering surface mount devices, and also AN-1112 for micro SMD considerations.

Note 4: If the $\overline{\text{RESET}}$ pin is to be used at temperatures of -20°C and below V_S is required to be 2.0V or greater.

Note 5: For device pinout please refer to table 1

Application Information

MONOSTABLE OPERATION

In this mode of operation, the timer functions as a one-shot (*Figure 1*). The external capacitor is initially held discharged by internal circuitry. Upon application of a negative trigger pulse of less than 1/3 V_S to the Trigger terminal, the flip-flop is set which both releases the short circuit across the capacitor and drives the output high.

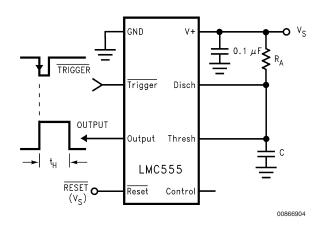

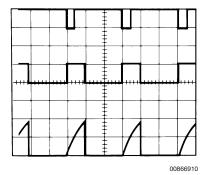

FIGURE 1. Monostable (One-Shot)

The voltage across the capacitor then increases exponentially for a period of $t_H = 1.1 R_A C$, which is also the time that the output stays high, at the end of which time the voltage equals 2/3 V_S. The comparator then resets the flip-flop which in turn discharges the capacitor and drives the output to its low state. *Figure 2* shows the waveforms generated in this mode of operation. Since the charge and the threshold level of the comparator are both directly proportional to supply voltage, the timing internal is independent of supply.

 $\label{eq:V_CC} \begin{array}{ll} V_{CC} = 5V & \mbox{Top} \\ \mbox{TIME} = 0.1 \mbox{ ms/Div.} & \mbox{Midd} \\ \mbox{R}_A = 9.1 \mbox{ k}\Omega & \mbox{Bot} \\ \mbox{C} = 0.01 \mbox{ } \mu \mbox{F} \end{array}$

Top Trace: Input 5 V/Div. Middle Trace: Output 5 V/Div. Bottom Trace: Capacitor Voltage 2 V/Div.

FIGURE 2. Monostable Waveforms

Reset overrides Trigger, which can override threshold. Therefore the trigger pulse must be shorter than the desired t_{H} . The minimum pulse width for the Trigger is 20ns, and it is 400ns for the Reset. During the timing cycle when the output is high, the further application of a trigger pulse will not effect the circuit so long as the trigger input is returned high at least 10µs before the end of the timing interval. However the circuit can be reset during this time by the application of a

negative pulse to the reset terminal. The output will then remain in the low state until a trigger pulse is again applied. When the reset function is not use, it is recommended that it be connected to V_+ to avoid any possibility of false triggering. *Figure 3* is a nomograph for easy determination of RC values for various time delays.

Note: In monstable operation, the trigger should be driven high before the end of timing cycle.

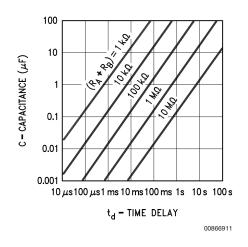

FIGURE 3. Time Delay

ASTABLE OPERATION

If the circuit is connected as shown in *Figure 4* (Trigger and Threshold terminals connected together) it will trigger itself and free run as a multivibrator. The external capacitor charges through $R_A + R_B$ and discharges through R_B . Thus the duty cycle may be precisely set by the ratio of these two resistors.

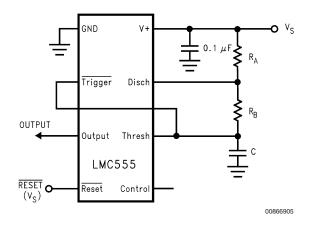

FIGURE 4. Astable (Variable Duty Cycle Oscillator)

In this mode of operation, the capacitor charges and discharges between 1/3 $V_{\rm S}$ and 2/3 $V_{\rm S}.$ As in the triggered mode, the charge and discharge times, and therefore the frequency are independent of the supply voltage.

Figure 5 shows the waveform generated in this mode of operation.

Application Information (Continued)

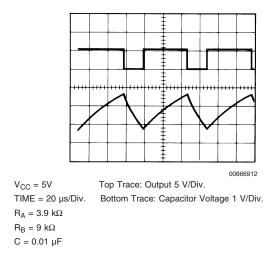

FIGURE 5. Astable Waveforms

The charge time (output high) is given by
$$t_1=0.693~(R_A+R_B)C$$
 And the discharge time (output low) by:

t₂ = 0.693 (R_B)C

Thus the total period is:

$$T = t_1 + t_2 = 0.693 (R_A + R_B)C$$

The frequency of oscillation is:

$$f = \frac{1}{T} = \frac{1.44}{(R_A + 2 R_B) C}$$

Figure 6 may be used for quick determination of these RC Values. The duty cycle, as a fraction of total period that the output is low, is:

 $\mathsf{D} = \frac{\mathsf{R}_{\mathsf{B}}}{\mathsf{R}_{\mathsf{A}} + 2\mathsf{R}_{\mathsf{B}}}$

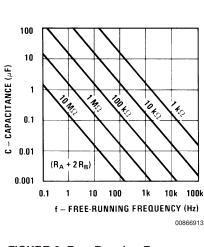

FIGURE 6. Free Running Frequency

FREQUENCY DIVIDER

The monostable circuit of *Figure 1* can be used as a frequency divider by adjusting the length of the timing cycle. *Figure 7* shows the waveforms generated in a divide by three circuit.

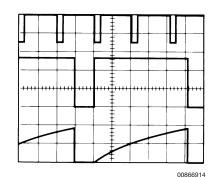

FIGURE 7. Frequency Divider Waveforms

PULSE WIDTH MODULATOR

When the timer is connected in the monostable mode and triggered with a continuous pulse train, the output pulse width can be modulated by a signal applied to the Control Voltage Terminal. *Figure 8* shows the circuit, and in *Figure 9* are some waveform examples.

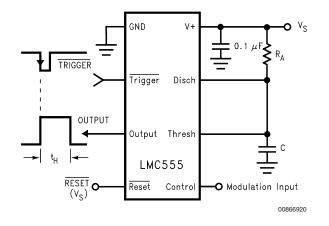

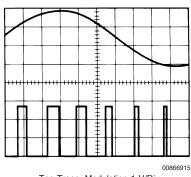

FIGURE 8. Pulse Width Modulator

Application Information (Continued)

 $\label{eq:VCC} V_{CC} = 5V \qquad \mbox{Top Trace: Modulation 1 V/Div.}$ TIME = 0.2 ms/Div. Bottom Trace: Output Voltage 2 V/Div. $R_A = 9.1 \ k\Omega$ $C = 0.01 \ \mu F$

FIGURE 9. Pulse Width Modulator Waveforms

PULSE POSITION MODULATOR

This application uses the timer connected for astable operation, as in *Figure 10*, with a modulating signal again applied to the control voltage terminal. The pulse position varies with the modulating signal, since the threshold voltage and hence the time delay is varied. *Figure 11* shows the waveforms generated for a triangle wave modulation signal.

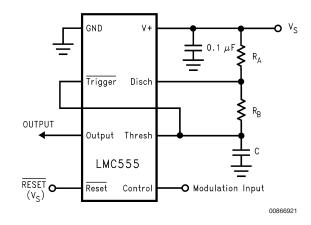

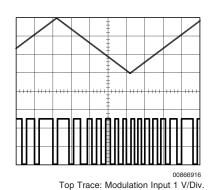

FIGURE 10. Pulse Position Modulator

 $V_{CC} = 5V$ TIME = 0.1 ms/Div. $R_A = 3.9 \text{ k}\Omega$ $R_B = 3 \text{ k}\Omega$ $C = 0.01 \text{ }\mu\text{F}$

Bottom Trace: Output Voltage 2 V/Div.

FIGURE 11. Pulse Position Modulator Waveforms

50% DUTY CYCLE OSCILLATOR

The frequency of oscillation is $f = 1/(1.4 \ R_{\rm C}C)$
