

## FLASH AND SRAM COMBO MEMORY

## MT28C6428P20 MT28C6428P18

Low Voltage, Extended Temperature  
0.18µm Process Technology

### FEATURES

- Flexible dual-bank architecture
- Support for true concurrent operations with no latency:
  - Read bank *b* during program bank *a* and vice versa
  - Read bank *b* during erase bank *a* and vice versa
- Organization: 4,096K x 16 (Flash)  
512K x 16 (SRAM)

### Basic configuration:

#### Flash

- Bank *a* (16Mb Flash for data storage)
  - Eight 4K-word parameter blocks
  - Thirty-one 32K-word blocks
- Bank *b* (48Mb Flash for program storage)
  - Ninety-six 32K-word main blocks

#### SRAM

- 8Mb SRAM for data storage
  - 512K-words

- F\_Vcc, VccQ, F\_Vpp, S\_Vcc voltages

#### MT28C6428P20

- 1.80V (MIN)/2.20V (MAX) F\_Vcc read voltage
- 1.80V (MIN)/2.20V (MAX) S\_Vcc read voltage
- 1.80V (MIN)/2.20V (MAX) VccQ

#### MT28C6428P18

- 1.70V (MIN)/1.90V (MAX) F\_Vcc read voltage
- 1.70V (MIN)/1.90V (MAX) S\_Vcc read voltage
- 1.70V (MIN)/1.90V (MAX) VccQ

#### MT28C6428P20/P18

- 1.80V (TYP) F\_Vpp (in-system PROGRAM/ERASE)
- 1.0V (MIN) S\_Vcc (SRAM data retention)
- 12V ±5% (HV) F\_Vpp (in-house programming and accelerated programming algorithm [APA] activation)

- Asynchronous access time
  - Flash access time: 80ns @ 1.80V F\_Vcc
  - SRAM access time: 80ns @ 1.80V S\_Vcc
- Page Mode read access
  - Interpage read access: 80ns @ 1.80V F\_Vcc
  - Intrapage read access: 30ns @ 1.80V F\_Vcc
- Low power consumption
- Enhanced suspend options
  - ERASE-SUSPEND-to-READ within same bank
  - PROGRAM-SUSPEND-to-READ within same bank
  - ERASE-SUSPEND-to-PROGRAM within same bank
- Read/Write SRAM during program/erase of Flash

### BALL ASSIGNMENT 67-Ball FBGA (Top View)

Top View  
(Ball Down)

- Dual 64-bit chip protection registers for security purposes
- PROGRAM/ERASE cycles
  - 100,000 WRITE/ERASE cycles per block
- Cross-compatible command set support
  - Extended command set
  - Common flash interface (CFI) compliant

### OPTIONS

- Timing
  - 80ns
  - 85ns
- Boot Block Configuration
  - Top T
  - Bottom B
- Operating Voltage Range
  - F\_Vcc = 1.70V–1.90V 18
  - F\_Vcc = 1.80V–2.20V 20
- Operating Temperature Range
  - Commercial (0°C to +70°C) None
  - Extended (-40°C to +85°C) ET
- Package
  - 67-ball FBGA (8 x 8 grid) FM

### MARKING

Part Number Example:

**MT28C6428P20FM-80 BET**

## GENERAL DESCRIPTION

The MT28C6428P20 and MT28C6428P18 combination Flash and SRAM memory devices provide a compact, low-power solution for systems where PCB real estate is at a premium. The dual-bank Flash devices are high-performance, high-density, nonvolatile memory with a revolutionary architecture that can significantly improve system performance.

This new architecture features:

- A two-memory-bank configuration supporting dual-bank operation;
- A high-performance bus interface providing a fast page data transfer; and
- A conventional asynchronous bus interface.

The devices also provide soft protection for blocks by configuring soft protection registers with dedicated command sequences. For security purposes, dual 64-bit chip protection registers are provided.

The embedded WORD WRITE and BLOCK ERASE functions are fully automated by an on-chip write state machine (WSM). The WSM simplifies these operations and relieves the system processor of secondary tasks. An on-chip status register, one for each bank, can be used to monitor the WSM status to determine the progress of a PROGRAM/ERASE command.

The erase/program suspend functionality allows compatibility with existing EEPROM emulation software packages.

The devices take advantage of a dedicated power source for the Flash memory (F\_Vcc) and a dedicated power source for the SRAM (S\_Vcc), both at 1.70V–2.20V for optimized power consumption and improved noise immunity. A dedicated I/O power supply (VccQ) is provided with an extended range (1.70V–2.20V), to allow a direct interface to most common logic controllers and to ensure improved noise immunity. The separate S\_Vcc pin for the SRAM provides data retention capability when required. The data retention S\_Vcc is speci-

fied as low as 1.0V. The MT28C6428P20 and MT28C6428P18 devices support two F\_Vpp voltage ranges, an in-circuit voltage of 0.9V–2.2V and a production compatibility voltage of 12V ±5%. The 12V ±5% F\_Vpp2 is supported for a maximum of 100 cycles and 10 cumulative hours.

The MT28C6428P20 and MT28C6428P18 contain an asynchronous 8Mb SRAM organized as 512K-words by 16 bits. The devices are fabricated using an advanced CMOS process and high-speed/ultra-low-power circuit technology, and then are packaged in a 67-ball FBGA package with 0.80mm pitch.

## ARCHITECTURE AND MEMORY ORGANIZATION

The Flash devices contain two separate banks of memory (bank *a* and bank *b*) for simultaneous READ and WRITE operations, which are available in the following bank segmentation configuration:

- Bank *a* comprises one-fourth of the memory and contains 8 x 4K-word parameter blocks, while the remainder of bank *a* is split into 31 x 32K-word blocks.
- Bank *b* represents three-fourths of the memory, is equally sectored, and contains 96 x 32K-word blocks.

Figures 2 and 3 show the bottom and top memory organizations.

## DEVICE MARKING

Due to the size of the package, Micron's standard part number is not printed on the top of each device. Instead, an abbreviated device mark comprised of a five-digit alphanumeric code is used. The abbreviated device marks are cross referenced to Micron part numbers in Table 1.

**Table 1**  
**Cross Reference for Abbreviated Device Marks**

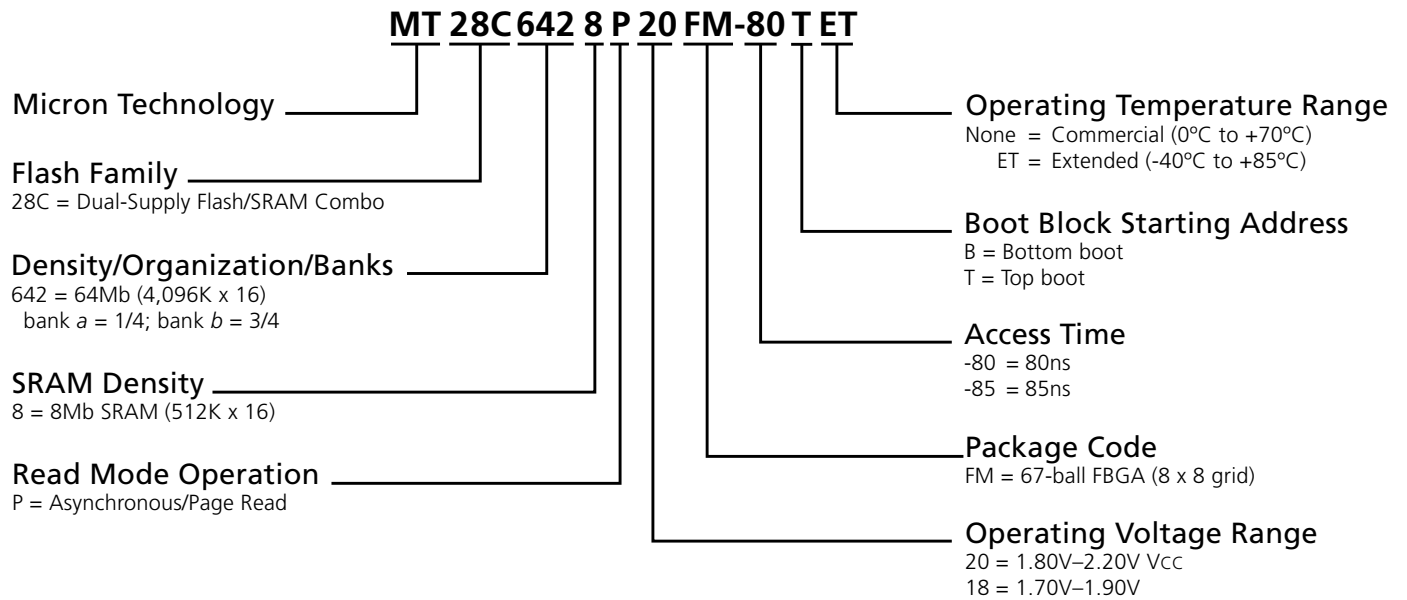

| PART NUMBER           | PRODUCT MARKING | SAMPLE MARKING | MECHANICAL SAMPLE MARKING |
|-----------------------|-----------------|----------------|---------------------------|
| MT28C6428P20FM-80 BET | FW454           | FX454          | FY454                     |
| MT28C6428P20FM-80 TET | FW453           | FX453          | FY453                     |
| MT28C6428P18FM-85 BET | FW455           | FX455          | FY455                     |
| MT28C6428P18FM-85 TET | FW452           | FX452          | FY452                     |

## PART NUMBERING INFORMATION

Micron's low-power devices are available with several different combinations of features (see Figure 1).

Valid combinations of features and their corresponding part numbers are listed in Table 2.

**Figure 1  
Part Number Chart**

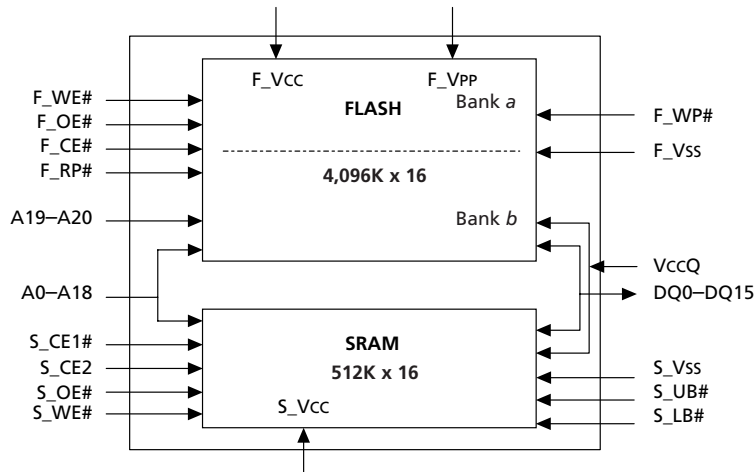

**Table 2  
Valid Part Number Combinations<sup>1</sup>**

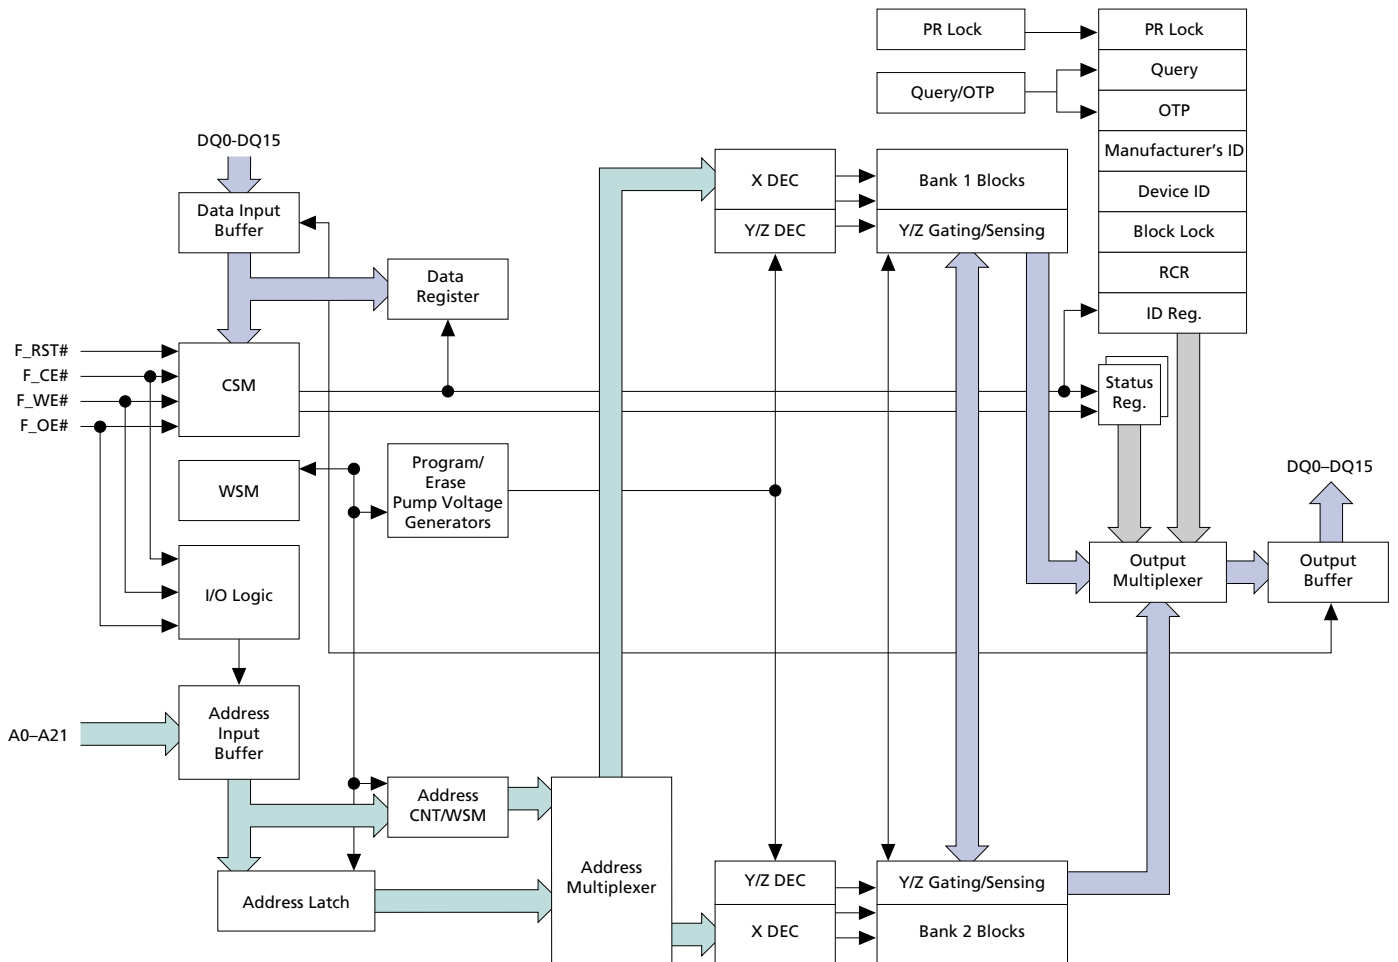

| PART NUMBER           | ACCESS TIME (ns) | BOOT BLOCK STARTING ADDRESS | OPERATING TEMPERATURE RANGE |
|-----------------------|------------------|-----------------------------|-----------------------------|
| MT28C6428P20FM-80 BET | 80               | Bottom                      | -40°C to +85°C              |
| MT28C6428P20FM-80 TET | 80               | Top                         | -40°C to +85°C              |
| MT28C6428P18FM-85 BET | 85               | Bottom                      | -40°C to +85°C              |
| MT28C6428P18FM-85 TET | 85               | Top                         | -40°C to +85°C              |

**NOTE:** 1. For part number combinations not listed in this table, please contact your Micron representative.

## FLASH FUNCTIONAL BLOCK DIAGRAM

## BALL DESCRIPTIONS

| 67-BALL FBGA NUMBERS   | SYMBOL   | TYPE         | DESCRIPTION  |
|--|----------|--------------|--|
| H6, G9, G8, G7, H5, H4, G6, G5, B4, B6, B5, A4, A8, A7, A6, A5, B3, G4, G3, E5, A3, C5 | A0–A21   | Input        | Address Inputs: Inputs for the addresses during READ and WRITE operations. Addresses are internally latched during READ and WRITE cycles. Flash: A0–A21; SRAM: A0–A18.   |
| H7   | F_CE#    | Input        | Flash Chip Enable: Activates the device when LOW. When CE# is HIGH, the device is disabled and goes into standby power mode.   |
| H9   | F_OE#    | Input        | Flash Output Enable: Enables Flash output buffers when LOW. When F_OE# is HIGH, the output buffers are disabled.   |
| C3   | F_WE#    | Input        | Flash Write Enable: Determines if a given cycle is a Flash WRITE cycle. F_WE# is active LOW.   |
| D4   | F_RP#    | Input        | Reset. When F_RP# is a logic LOW, the device is in reset, which drives the outputs to High-Z and resets the WSM. When F_RP# is a logic HIGH, the device is in standard operation. When F_RP# transitions from logic LOW to logic HIGH, the device resets all blocks to locked and defaults to the read array mode. |
| E3   | F_WP#    | Input        | Flash Write Protect. Controls the lock down function of the flexible locking feature.  |
| G10  | S_CE1#   | Input        | SRAM Chip Enable1: Activates the SRAM when it is LOW. HIGH level deselects the SRAM and reduces the power consumption to standby levels.   |
| D8   | S_CE2    | Input        | SRAM Chip Enable2: Activates the SRAM when it is HIGH. LOW level deselects the SRAM and reduces the power consumption to standby levels.   |
| F5   | S_OE#    | Input        | SRAM Output Enable: Enables SRAM output buffers when LOW. When S_OE# is HIGH, the output buffers are disabled.   |
| B8   | S_WE#    | Input        | SRAM Write Enable: Determines if a given cycle is an SRAM WRITE cycle. S_WE# is active LOW.  |
| F3   | S_LB#    | Input        | SRAM Lower Byte: When LOW, it selects the SRAM address lower byte (DQ0–DQ7).   |
| F4   | S_UB#    | Input        | SRAM Upper Byte: When LOW, it selects the SRAM address upper byte (DQ8–DQ15).  |
| F9, F10, E9, E10, C9, C10, C8, B10, F8, F7, E8, E6, D7, C7, B9, B7                     | DQ0–DQ15 | Input/Output | Data Inputs/Outputs: Input array data on the second CE# and WE# cycle during PROGRAM command. Input commands to the command user interface when CE# and WE# are active. Output data when CE# and OE# are active.   |

(continued on next page)

## BALL DESCRIPTIONS (continued)

| 67-BALL FBGA NUMBERS                        | SYMBOL | TYPE         | DESCRIPTION  |
|---|--------|--------------|--|
| E4  | F_VPP  | Input/Supply | Flash Program/Erase Power Supply: [0.9V–2.2V or 11.4V–12.6V]. Operates as input at logic levels to control complete device protection. Provides backward compatibility for factory programming when driven to 11.4V–12.6V. A lower F_VPP voltage range (0.0V–2.2V) is available. Contact factory for more information. |
| D10, H3                                     | F_Vcc  | Supply       | Flash Power Supply: [1.70V–1.90V or 1.80V–2.20V]. Supplies power for device operation.   |
| A9, H8                                      | F_Vss  | Supply       | Flash Specific Ground: Do not float any ground ball.   |
| D9  | S_Vcc  | Supply       | SRAM Power Supply: [1.70V–1.90V or 1.80V–2.20V]. Supplies power for device operation.  |
| D3  | S_Vss  | Supply       | SRAM Specific Ground: Do not float any ground ball.  |
| A10   | VccQ   | Supply       | I/O Power Supply: [1.70–1.90V or 1.80V–2.20V].   |
| A1, A2, A11, A12, C4, H1, H2, H10, H11, H12 | NC     | –            | No Connect: Lead is not internally connected; it may be driven or floated.   |
| C6, D5, D6, E7, F6                          | –      | –            | Contact balls not mounted; corresponding position on PCB can be used to reduce routing complexity.   |

|                |                          |       |       |       | H                       | X     | X     | X     | X     | X     | Other              | High-Z   |       |
| Output Disable | Flash any mode allowable |       |       |       | SRAM any mode allowable |       |       |       |       |       | Other              |          | 4     |
|                |                          |       |       |       | X                       | L     | X     | X     | X     | X     | Other              | High-Z   |       |
| Output Disable | Flash any mode allowable |       |       |       | SRAM any mode allowable |       |       |       |       |       | Other              |          | 4     |
|                |                          |       |       |       | L                       | H     | X     | X     | X     | X     | Other              | High-Z   |       |

- NOTE:**
- Two devices may not drive the memory bus at the same time.
  - Allowable Flash read modes include read array, read query, read configuration, and read status.
  - Outputs are dependent on a separate device controlling bus outputs.
  - Modes of the Flash and SRAM can be interleaved so that while one is disabled, the other controls outputs.
  - SRAM is enabled and/or disabled with the logical function: S\_CE1# or S\_CE2.
  - Simultaneous operations can exist, as long as the operations are interleaved such that only one device attempts to control the bus outputs at a time.
  - Data output on lower byte only; upper byte High-Z.
  - Data output on upper byte only; lower byte High-Z.
  - Data input on lower byte only.
  - Data input on upper byte only.

## FLASH MEMORY OPERATING MODES

### COMMAND STATE MACHINE

Commands are issued to the command state machine (CSM) using standard microprocessor write timings. The CSM acts as an interface between external microprocessors and the internal write state machine (WSM). The available commands are listed in Table 3, their definitions are given in Table 4 and their descriptions in Table 5. Program and erase algorithms are automated by the on-chip WSM. Table 7 shows the CSM transition states.

Once a valid PROGRAM/ERASE command is entered, the WSM executes the appropriate algorithm, which generates the necessary timing signals to control the device internally. A command is valid only if the exact sequence of WRITES is completed. After the WSM completes its task, the write state machine status (WSMS) bit (SR7) (see Table 8) is set to a logic HIGH level ( $V_{IH}$ ), allowing the CSM to respond to the full command set again.

### OPERATIONS

Device operations are selected by entering a standard JEDEC 8-bit command code with conventional microprocessor timings into an on-chip CSM through I/Os DQ0–DQ7. The number of bus cycles required to activate a command is typically one or two. The first operation is always a WRITE. Control signals  $F_{CE\#}$  and  $F_{WE\#}$  must be at a logic LOW level ( $V_{IL}$ ), and  $F_{OE\#}$  and  $F_{RP\#}$  must be at logic HIGH ( $V_{IH}$ ). The second operation, when needed, can be a WRITE or a READ depending upon the command. During a READ operation, control signals  $F_{CE\#}$  and  $F_{OE\#}$  must be at a logic LOW level ( $V_{IL}$ ), and  $F_{WE\#}$  and  $F_{RP\#}$  must be at logic HIGH ( $V_{IH}$ ).

Table 7 illustrates the bus operations for all the modes: write, read, reset, standby, and output disable.

When the device is powered up, internal reset circuitry initializes the chip to a read array mode of operation. Changing the mode of operation requires that a command code be entered into the CSM. For each one of the two Flash memory partitions, an on-chip status register is available. These two registers allow the monitoring of the progress of various operations that can take place on a memory bank. One of the two status registers is interrogated by entering a READ STATUS REGISTER command onto the CSM (cycle 1), specifying an address within the memory partition boundary, and reading the register data on I/O pins DQ0–DQ7 (cycle 2). Status register bits SR0–SR7 correspond to DQ0–DQ7 (see Table 8).

### COMMAND DEFINITION

Once a specific command code has been entered, the WSM executes an internal algorithm, generating the necessary timing signals to program, erase, and verify data. See Table 4 for the CSM command definitions and data for each of the bus cycles.

### STATUS REGISTER

The status register allows the user to determine whether the state of a PROGRAM/ERASE operation is pending or complete. The status register is monitored by toggling  $F_{OE\#}$  and  $F_{CE\#}$  and reading the resulting status code on I/Os DQ0–DQ7. The high-order I/Os (DQ8–DQ15) are set to 00h internally, so only the low-order I/Os (DQ0–DQ7) need to be interpreted. Address lines select the status register pertinent to the selected memory partition.

**Table 3**  
**Command State Machine Codes For Device Mode Selection**

| COMMAND DQ0–DQ7 | CODE ON DEVICE MODE                     |
|-----------------|---|
| 10h             | Accelerated Programming Algorithm (APA) |
| 20h             | Block erase setup                       |
| 40h             | Program setup                           |
| 50h             | Clear status register                   |
| 60h             | Protection configuration setup          |
| 60h             | Enable/disable deep power-down          |
| 70h             | Read status register                    |
| 90h             | Read protection configuration register  |
| 98h             | Read query                              |
| B0h             | Program/erase suspend                   |
| C0h             | Protection register program/lock        |
| D0h             | Program/erase resume – erase confirm    |
| D1h             | Check block erase confirm               |
| FFh             | Read array                              |

Register data is updated and latched on the falling edge of F\_OE# or F\_CE#, whichever occurs last. The latest falling edge of either of these two signals updates the latch within a given READ cycle. Latching the data prevents errors from occurring if the register input changes during a status register read.

The status register provides the internal state of the WSM to the external microprocessor. During periods when the WSM is active, the status register can be polled to determine the WSM status. Table 8 defines the status register bits.

After monitoring the status register during a PROGRAM/ERASE operation, the data appearing on DQ0–DQ7 remains as status register data until a new command is issued to the CSM. To return the device to other modes of operation, a new command must be issued to the CSM.

## COMMAND STATE MACHINE OPERATIONS

The CSM decodes instructions for the commands listed in Table 3. The 8-bit command code is input to the device on DQ0–DQ7 (see Table 4 for command definitions). During a PROGRAM or ERASE cycle, the CSM informs the WSM that a PROGRAM or ERASE cycle has been requested.

During a PROGRAM cycle, the WSM controls the program sequences and the CSM responds to a PROGRAM SUSPEND command only.

During an ERASE cycle, the CSM responds to an ERASE SUSPEND command only. When the WSM has completed its task, the WSMS bit (SR7) is set to a logic HIGH level and the CSM responds to the full command set. The CSM stays in the current command state until the microprocessor issues another command.

The WSM successfully initiates an ERASE or PROGRAM operation only when F\_VPP is within its correct voltage range.

**Table 4**  
**Command Definitions**

| COMMAND                                 | FIRST BUS CYCLE |                      |      | SECOND BUS CYCLE |                      |                   |
|---|-----------------|----------------------|------|------------------|----------------------|-------------------|
|   | OPERATION       | ADDRESS <sup>1</sup> | DATA | OPERATION        | ADDRESS <sup>1</sup> | DATA <sup>1</sup> |
| READ ARRAY                              | WRITE           | WA                   | FFh  |                  |                      |                   |

| UNLOCK BLOCK                            | WRITE           | BA                   | 60h  | WRITE            | BA                   | D0h               |
| LOCK DOWN BLOCK                         | WRITE           | BA                   | 60h  | WRITE            | BA                   | 2Fh               |
| CHECK BLOCK ERASE                       | WRITE           | BA                   | 20h  | WRITE            | BA                   | D1h               |
| PROTECTION REGISTER PROGRAM             | WRITE           | PA                   | C0h  | WRITE            | PA                   | PD                |
| PROTECTION REGISTER LOCK                | WRITE           | LPA                  | C0h  | WRITE            | LPA                  | FFFDh             |
| ENABLE/DISABLE DEEP POWER-DOWN          | WRITE           | DPW                  | 60h  | WRITE            | DPW                  | 03h               |

**NOTE:** 1. BA: Address within the block  
 DPW: BBCFh = Disable deep power-down  
 BDDFh = Enable deep power-down  
 IA: Identification code address  
 ID: Identification code data  
 LPA: Lock protection register address  
 PA: Protection register address  
 PD: Data to be written at location PA  
 QA: Query code address  
 QD: Query code data  
 SRD: Data read from the status register  
 WA: Word address of memory location to be written, or read  
 WD: Data to be written at the location WA  
 X: "Don't Care"

**Table 5  
Command Descriptions**

| CODE | DEVICE MODE                        | BUS CYCLE | DESCRIPTION   |
|------|------------------------------------|-----------|---|
| 10h  | APA                                | First     | Prepares for an accelerated program operation.  |
| 20h  | Erase Setup                        | First     | Prepares the CSM for the ERASE command. If the next command is not a CHECK BLOCK ERASE OR ERASE CONFIRM command, the command will be ignored, and the device will go to read status mode and wait for another command.  |
| 40h  | Program Setup                      | First     | A two-cycle command: The first cycle prepares for a PROGRAM operation, the second cycle latches addresses and data and initiates the WSM to execute the program algorithm. The Flash outputs status register data on the falling edge of F_OE# or F_CE#, whichever occurs first.  |
| 50h  | Clear Status Register              | First     | The WSM can set the program status (SR4), and erase status (SR5) bits in the status register to "1," but it cannot clear them to "0." Issuing this command clears those bits to "0."  |
| 60h  | Protection Configuration Setup     | First     | Prepares the CSM for changes to the block locking status. If the next command is not BLOCK UNLOCK, BLOCK LOCK or BLOCK LOCK DOWN, the command will be ignored, and the device will go to read status mode.  |
|      | Set Read Configuration Register    | First     | Puts the device into the set read configuration mode so that it will be possible to set the option bits related to burst read mode.   |
| 70h  | Read Status Register               | First     | Places the device into read status register mode. Reading the device outputs the contents of the status register for the addressed bank. The device automatically enters this mode for the addressed bank after a PROGRAM or ERASE operation has been initiated.  |
| 90h  | Read Protection Configuration      | First     | Puts the device into the read protection configuration mode so that reading the device outputs the manufacturer/device codes or block lock status.  |
| 98h  | Read Query                         | First     | Puts the device into the read query mode so that reading the device outputs common Flash interface information.   |
| B0h  | Program Suspend                    | First     | Suspends the currently executing PROGRAM/ERASE/CHECK BLOCK ERASE operation. The status register indicates when the operation has been successfully suspended by setting either the program suspend (SR2) or erase suspend (SR6) and the WSMS bit (SR7) to a "1" (ready). The WSM continues to idle in the suspend state, regardless of the state of all input control pins except F_RP#, which immediately shuts down the WSM and the remainder of the chip if F_RP# is driven to V <sub>IL</sub> . |
|      | Erase Suspend                      | First     |   |
|      | Check Block Erase Suspend          | First     |   |
| C0h  | Program Device Protection Register | First     | Writes a specific code into the device protection register.   |
|      | Lock Device Protection Register    | First     | Locks the device protection register; data can no longer be changed.  |

(continued on the next page)

**Table 5  
Command Descriptions (continued)**

| CODE | DEVICE MODE                                   | BUS CYCLE | DESCRIPTION  |
|------|---|-----------|--|
| D0h  | Erase Confirm                                 | Second    | If the previous command was an ERASE SETUP command, then the CSM closes the address and data latches, and it begins erasing the block indicated on the address pins. During programming/erase, the device responds only to the READ STATUS REGISTER, PROGRAM SUSPEND, or ERASE SUSPEND commands and outputs status register data on the falling edge of F_OE# or F_CE#, whichever occurs last. |
|      | Program/Erase/<br>Check Block Erase<br>Resume | First     | If a PROGRAM, ERASE or CHECK BLOCK ERASE operation was previously suspended, this command resumes the operation.   |
| FFh  | Read Array                                    | First     | During the array mode, array data is output on the data bus.   |
| 01h  | Lock Block                                    | Second    | If the previous command was PROTECTION CONFIGURATION SETUP, the CSM latches the address and locks the block indicated on the address bus.  |
| 2Fh  | Lock Down                                     | Second    | If the previous command was PROTECTION CONFIGURATION SETUP, the CSM latches the address and locks down the block indicated on the address bus.   |
| D0h  | Unlock Block                                  | Second    | If the previous command was PROTECTION CONFIGURATION SETUP, the CSM latches the address and unlocks the block indicated on the address bus. If the block had been previously set to lock down, this operation has no effect.   |
| 00h  | Invalid/Reserved                              |           | Unassigned command that should not be used.  |
| D1h  | Check Block<br>Erase Confirm                  | Second    | If the previous command was ERASE SETUP command, the CSM closes the address latches and checks that the block is completely erased.  |

### **CLEAR STATUS REGISTER**

The internal circuitry can set, but not clear, the block lock status bit (SR1), the F\_VPP status bit (SR3), the program status bit (SR4), and the erase status bit (SR5) of the status register. The CLEAR STATUS REGISTER command (50h) allows the external microprocessor to clear these status bits and synchronize to the internal operations. When the status bits are cleared, the device returns to the read array mode.

### **READ OPERATIONS**

The following READ operations are available: READ ARRAY, READ PROTECTION CONFIGURATION REGISTER, READ QUERY and READ STATUS REGISTER.

#### **READ ARRAY**

The array is read by entering the command code FFh on DQ0–DQ7. Control signals F\_CE# and F\_OE# must be at a logic LOW level (V<sub>IL</sub>), and F\_WE# and F\_RP# must be at a logic HIGH level (V<sub>IH</sub>) to read data from the array. Data is available on DQ0–DQ15. Any valid address within any of the blocks selects that address and allows data to be read from that address. Upon initial power-up or device reset, the device defaults to the read array mode.

#### **READ CHIP PROTECTION IDENTIFICATION DATA**

The chip identification mode outputs three types of information: the manufacturer/device identifier, the block locking status, and the protection register. Two bus cycles are required for this operation: the chip identification data is read by entering the command code 90h on DQ0–DQ7 to the bank containing address 00h and the identification code address on the address

lines. Control signals F\_CE# and F\_OE# must be at a logic LOW level (V<sub>IL</sub>), and F\_WE# and F\_RP# must be at a logic HIGH level (V<sub>IH</sub>) to read data from the protection configuration register. Data is available on DQ0–DQ15. After data is read from protection configuration register, the READ ARRAY command, FFh, must be issued to the bank containing address 00h prior to issuing other commands. See Table 10 for further details.

#### **READ QUERY**

The read query mode outputs common flash interface (CFI) data when the device is read (see Table 12). Two bus cycles are required for this operation. It is possible to access the query by writing the read query command code 98h on DQ0–DQ7 to the bank containing address 0h. Control signals F\_CE# and F\_OE# must be at a logic LOW level (V<sub>IL</sub>), and F\_WE# and F\_RP# must be at a logic HIGH level (V<sub>IH</sub>) to read data from the query. The CFI data structure contains information such as block size, density, command set, and electrical specifications. To return to read array mode, write the read array command code FFh on DQ0–DQ7.

#### **READ STATUS REGISTER**

The status register is read by entering the command code 70h on DQ0–DQ7. Two bus cycles are required for this operation: one to enter the command code and a second to read the status register. In a READ cycle, the address is latched and register data is updated on the falling edge of F\_OE# or F\_CE#, whichever occurs last. Register data is updated and latched on the falling edge of F\_OE# or F\_CE#, whichever occurs last.

## Table 6 Command State Machine Transition Table

| Command input to the present partition (and next state of the present partition) |                  |               |                            |                |                    |                           |                 |                            |   |                 |                            |                | Present state of the present partition |                |           |                     | Present state of the other partition |       |
|--|------------------|---------------|----------------------------|----------------|--------------------|---------------------------|-----------------|----------------------------|---|-----------------|----------------------------|----------------|--|----------------|-----------|---------------------|--------------------------------------|-------|
| 2Fh Lock down confirm  | 01h Lock confirm | C0h OTP setup | 60h Lock/Unlock /Lock down | 98h Read query | 90h Read device ID | 50h Clear status register | 70h Read status | B0h Program /Erase suspend | D0h BE confirm, P/E resume, ULB confirm | 20h Erase setup | 10h/40h APA/ Program setup | FFh Read array | SR7                                    | Data when read | State     | Mode                |                                      |       |

## PROGRAMMING OPERATIONS

There are two CSM commands for programming: PROGRAM SETUP and ACCELERATED PROGRAMMING ALGORITHM (see Table 3).

### PROGRAM SETUP COMMAND

After the 40h command code is entered on DQ0–DQ7, the WSM takes over and correctly sequences the device to complete the PROGRAM operation. The WRITE operation may be monitored through the status register (see the Status Register section). During this time, the CSM will only respond to a PROGRAM SUSPEND command until the PROGRAM operation has been completed, after which time, all commands to the CSM become valid again. The PROGRAM operation can be suspended by issuing a PROGRAM SUSPEND command (B0h).

Once the WSM reaches the suspend state, it allows the CSM to respond only to READ ARRAY, READ STATUS REGISTER, READ PROTECTION CONFIGURATION, READ QUERY, PROGRAM SETUP, or PROGRAM RESUME. During the PROGRAM SUSPEND operation, array data should be read from an address other than the one being programmed. To resume the PROGRAM operation, a PROGRAM RESUME command (D0h) must be issued to cause the CSM to clear the suspend state previously set (see Figure 4 for programming operation and Figure 5 for program suspend and program resume).

Taking RP# to VIL during programming aborts the PROGRAM operation.

### ACCELERATED PROGRAMMING ALGORITHM

The accelerated programming algorithm (APA) is intended for in-system and in-factory use. Its 32 single-word internal buffer enables fast data stream programming.

The APA is activated when the WSM executes command code 10h. Upon activation, the word address and the data sequences must be provided to the WSM, without polling SR7. The same starting address must be provided for each data word. After all 32 sequences are issued, the status register reports a busy condition. Figure 6 shows the APA flowchart.

If the data stream is shorter than 32 words, use FFFFh to fill in the missing data. Also, be sure the starting address is aligned with a 32-word boundary.

The APA is fully concurrent. For example, it can be interrupted and resumed during programming. When loading the programming buffer, only a read access in the other bank is allowed.

For in-factory programming, the APA, along with an optimized set of programming parameters, minimizes chip programming time when  $11.4V \leq F_{VPP} \leq 12.6V$ .

For in-system programming, when  $0.9V \leq F_{VPP} \leq 2.2V$ , the APA and the 32 single-word buffer significantly improve both the system throughput and the average programming time when compared with standard programming practices. The accelerated programming functionality executes and verifies the APA without microprocessor intervention. This relieves the microprocessor from constantly monitoring the progress of the programming and erase activity, freeing up valuable memory bus bandwidth. This increases the system throughput.

## ERASE OPERATIONS

An ERASE operation must be used to initialize all bits in an array block to “1s.” After BLOCK ERASE confirm is issued, the CSM responds only to an ERASE SUSPEND command until the WSM completes its task.

Block erasure inside the memory array sets all bits within the address block to logic 1s. Erase is accomplished only by blocks; data at single address locations within the array cannot be erased individually. The block to be erased is selected by using any valid address within that block. Block erasure is initiated by a command sequence to the CSM: BLOCK ERASE SETUP (20h) followed by BLOCK ERASE CONFIRM (D0h) (see Table 5). A two-command erase sequence protects against accidental erasure of memory contents.

When the BLOCK ERASE CONFIRM command is complete, the WSM automatically executes a sequence of events to complete the block erasure. During this sequence, the block is programmed with logic 0s, data is verified, all bits in the block are erased, and finally verification is performed to ensure that all bits are correctly erased. Monitoring of the ERASE operation is possible through the status register (see the Status Register section).

During the execution of an ERASE operation, the ERASE SUSPEND command (B0h) can be entered to direct the WSM to suspend the ERASE operation. Once the WSM has reached the suspend state, it allows the CSM to respond only to the READ ARRAY, READ STATUS REGISTER, READ QUERY, READ CHIP PROTECTION CONFIGURATION, PROGRAM SETUP, PROGRAM RESUME, ERASE RESUME and LOCK SETUP (see the Block Locking section). During the ERASE SUSPEND operation, array data must be read from a block other than the one being erased. To resume the ERASE operation, an ERASE RESUME command (D0h) must be issued to cause the CSM to clear the suspend state previously set (see Figure 8). It is also possible that an ERASE in any bank can be suspended and a WRITE to another block in the same bank can be initiated. After

the completion of a WRITE, an ERASE can be resumed by writing an ERASE RESUME command.

After an ERASE command completion, it is possible to check if the block has been erased successfully, using the CHECK BLOCK ERASE command. Two bus cycles are required for this operation: one to set up the

CHECK BLOCK ERASE and the second one to start the execution of the command. If after the operation the bit SR5 is set to 0 the operation has been completed successfully, if it is set to 1, there has been an error during the BLOCK ERASE operation.

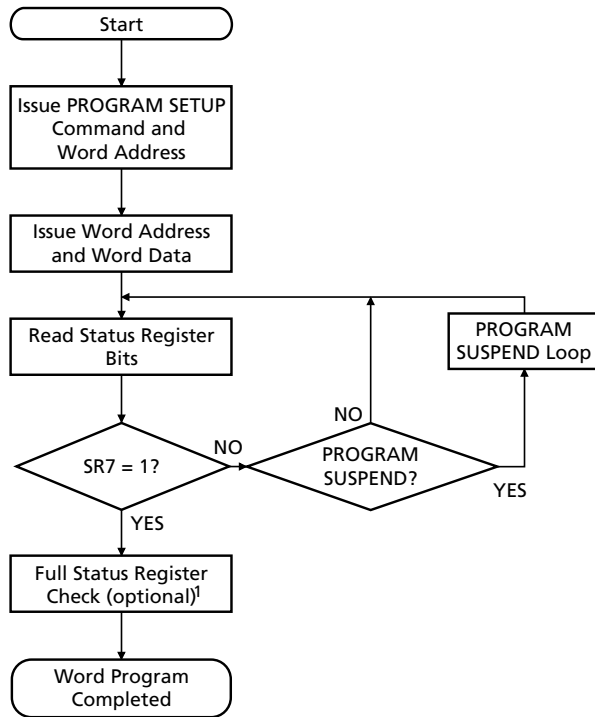

**Table 8  
Status Register Bit Definition**

| WSMS | ESS | ES | PS | VPPS | PSS | BLS | R |
|------|-----|----|----|------|-----|-----|---|
| 7    | 6   | 5  | 4  | 3    | 2   | 1   | 0 |

  

| STATUS BIT # | STATUS REGISTER BIT  | DESCRIPTION   |
|--------------|--|---|
| SR7          | WRITE STATE MACHINE STATUS (WSMS)<br>1 = Ready<br>0 = Busy   | Check write state machine bit first to determine word program or block erase completion, before checking program or erase status bits.  |
| SR6          | ERASE SUSPEND STATUS (ESS)<br>1 = BLOCK ERASE Suspended<br>0 = BLOCK ERASE in Progress/Completed                                 | When ERASE SUSPEND is issued, WSM halts execution and sets both WSMS and ESS bits to "1." ESS bit remains set to "1" until an ERASE RESUME command is issued.   |
| SR5          | ERASE/CHECK BLOCK ERASE STATUS (ES)<br>1 = Error in BLOCK ERASE/<br>CHECK BLOCK ERASE<br>0 = Successful BLOCK ERASE              | When this bit is set to "1" and ERASE CONFIRM is issued, WSM has applied the maximum number of erase pulses to the block and is still unable to verify successful block erasure. When this bit is set to "1" and CHECK BLOCK ERASE CONFIRM is issued, WSM has checked the block for its erase state, and the block is not erased.   |
| SR4          | PROGRAM STATUS (PS)<br>1 = Error in PROGRAM<br>0 = Successful PROGRAM  | When this bit is set to "1," WSM has attempted but failed to program a word.  |
| SR3          | F_VPP STATUS (VPPS)<br>1 = F_VPP Low Detect, Operation Abort<br>0 = F_VPP = OK   | The F_VPP status bit does not provide continuous indication of the F_VPP level. The WSM interrogates the F_VPP level only after the program or erase command sequences have been entered and informs the system if F_VPP < 0.9V. The F_VPP level is also checked before the PROGRAM/ERASE operation is verified by the WSM. A factory option allows PROGRAM or ERASE at 0V, in which case SR3 is held at "0." |
| SR2          | PROGRAM SUSPEND STATUS (PSS)<br>1 = PROGRAM Suspended<br>0 = PROGRAM in Progress/Completed                                       | When PROGRAM SUSPEND is issued, WSM halts execution and sets both WSM and PSS bits to "1." PSS bit remains set to "1" until a PROGRAM RESUME command is issued.   |
| SR1          | BLOCK LOCK STATUS (BLS)<br>1 = PROGRAM/ERASE Attempted on a Locked Block; Operation Aborted<br>0 = No Operation to Locked Blocks | If a PROGRAM or ERASE operation is attempted to one of the locked blocks, this is set by the WSM. The operation specified is aborted, and the device is returned to read status mode.   |
| SR0          | RESERVED FOR FUTURE ENHANCEMENT  | This bit is reserved for future use.  |

## READ-WHILE-WRITE/ERASE CONCURRENCY

It is possible for the device to read from one bank while erasing/writing to another bank. Once a bank enters the WRITE/ERASE operation, the other bank automatically enters read array mode. For example, during a READ CONCURRENCY operation, if a PROGRAM/ERASE command is issued in bank *a*, then bank *a* changes to the read status mode and bank *b* defaults to the read array mode. The device reads from bank *b* if the latched address resides in bank *b* (see Figure 10). Similarly, if a PROGRAM/ERASE command is issued in bank *b*, then bank *b* changes to read status mode and bank *a* defaults to read array mode. When returning to bank *a*, the device reads program/erase status if the latched address resides in bank *a*.

A correct bank address must be specified to read status register after returning from concurrent read in the other bank.

When reading the CFI or the chip protection register, concurrent operation is not allowed on the top boot device. Concurrent READ of the CFI or the chip protection register is only allowed when a PROGRAM or ERASE operation is performed on bank *b* on the bottom boot device. For a bottom boot device, reading of the CFI table or the chip protection register is only allowed if bank *b* is in read array mode. For a top boot device, reading of the CFI table or the chip protection register is only allowed if bank *a* is in read array mode.

## BLOCK LOCKING

The Flash memory of the MT28C6428P20 and MT28C6428P18 devices provide a flexible locking scheme which allows each block to be individually locked or unlocked with no latency.

The devices offer two-level protection for the blocks. The first level allows software-only control of block locking (for data which needs to be changed frequently), while the second level requires hardware interaction before locking can be changed (code which does not require frequent updates).

Control signals F\_WP#, DQ0, and DQ1 define the state of a block; for example, state [001] means F\_WP# = 0, DQ0 = 0 and DQ1 = 1.

Table 9 defines all of the possible locking states.

**NOTE:** All blocks are software-locked upon completion of the power-up sequence.

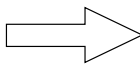

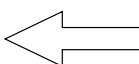

## LOCKED STATE

After a power-up sequence completion, or after a reset sequence, all blocks are locked (states [001] or [101]). This means full protection from alteration. Any PROGRAM or ERASE operations attempted on a locked block will return an error on bit SR1 of the status register. The status of a locked block can be changed to unlocked or lock down using the appropriate software commands. Writing the lock command sequence, 60h followed by 01h, can lock an unlocked block.

## UNLOCKED STATE

Unlocked blocks (states [000], [100], [110]) can be programmed or erased. All unlocked blocks return to the locked state when the device is reset or powered down. An unlocked block can be locked or locked down using the appropriate software command sequence, 60h followed by D0h. (See Table 4.)

**Figure 10**  
**READ-While-WRITE Concurrency**

| Bank a   | Bank b   |

| 1 - Erasing/writing to bank <i>a</i><br>2 - Erasing in bank <i>a</i> can be suspended, and a WRITE to another block in bank <i>a</i> can be initiated.<br>3 - After the WRITE in that block is complete, an ERASE can be resumed by writing an ERASE RESUME command. | <br>1 - Reading from bank <i>b</i>  |
| 1 - Reading bank <i>a</i><br>  | 1 - Erasing/writing to bank <i>b</i><br>2 - Erasing in bank <i>b</i> can be suspended, and a WRITE to another block in bank <i>b</i> can be initiated.<br>3 - After the WRITE in that block is complete, an ERASE can be resumed by writing an ERASE RESUME command. |

**Table 9  
Block Locking State Transition**

| F_WP# | DQ1 | DQ0 | NAME               | ERASE/PROGRAM ALLOWED | LOCK     | UNLOCK   | LOCK DOWN |
|-------|-----|-----|--------------------|-----------------------|----------|----------|-----------|
| 0     | 0   | 0   | Unlocked           | Yes                   | To [001] | –        | To [011]  |
| 0     | 0   | 1   | Locked (Default)   | No                    | –        | To [000] | To [011]  |
| 0     | 1   | 1   | Lock Down          | No                    | –        | –        | –         |
| 1     | 0   | 0   | Unlocked           | Yes                   | To [101] | –        | To [111]  |
| 1     | 0   | 1   | Locked             | No                    | –        | To [100] | To [111]  |
| 1     | 1   | 0   | Lock Down Disabled | Yes                   | To [111] | –        | To [111]  |
| 1     | 1   | 1   | Lock Down Disabled | No                    | –        | To [110] | –         |

### LOCKED DOWN STATE

Blocks locked down (state [011]) are protected from PROGRAM and ERASE operations, but their protection status cannot be changed using software commands alone. A locked or unlocked block can be locked down by writing the lock down command sequence, 60h followed by 2Fh. Locked down blocks revert to the locked state when the device is reset or powered down.

The LOCK DOWN function is dependent on the F\_WP# input. When F\_WP# = 0, blocks in lock down [011] are protected from program, erase, and lock status changes. When F\_WP# = 1, the LOCK DOWN function is disabled ([111]) and locked down blocks can be individually unlocked by a software command to the [110] state, where they can be erased and programmed. These blocks can then be relocked [111] and unlocked [110], as desired, as long as F\_WP# remains HIGH. When F\_WP# goes LOW, blocks that were previously locked down return to the lock down state [011] regardless of any changes made while F\_WP# was HIGH. Device reset or power-down resets all locks, including those in lock down, to the locked state (see Table 10).

### READING A BLOCK'S LOCK STATUS

The lock status of every block can be read in the read device identification mode. To enter this mode, write 90h to the bank containing address 00h. Subsequent READs at block address +00002h will output the lock status of that block. The lowest two outputs, DQ0 and DQ1, represent the lock status. DQ0 indicates the block lock/unlock status and is set by the LOCK command and cleared by the UNLOCK command. It is also automatically set when entering lock down. DQ1 indicates lock down status and is set by the LOCK DOWN command. It can only be cleared by reset or power-down, not by software. Table 9 shows the block locking state transition scheme. The READ ARRAY command,

FFh, must be issued to the bank containing address 00h prior to issuing other commands.

### LOCKING OPERATIONS DURING ERASE SUSPEND

Changes to block lock status can be performed during an ERASE SUSPEND by using the standard locking command sequences to unlock, lock, or lock down. This is useful in the case when another block needs to be updated while an ERASE operation is in progress.

To change block locking during an ERASE operation, first write the ERASE SUSPEND command (B0h), then check the status register until it indicates that the ERASE operation has been suspended. Next, write the desired lock command sequence to block lock, and the lock status will be changed. After completing any desired LOCK, READ, or PROGRAM operations, resume the ERASE operation with the ERASE RESUME command (D0h).

If a block is locked or locked down during an ERASE SUSPEND on the same block, the locking status bits are changed immediately. When the ERASE is resumed, the ERASE operation completes.

A locking operation cannot be performed during a PROGRAM SUSPEND.

### STATUS REGISTER ERROR CHECKING

Using nested locking or program command sequences during ERASE SUSPEND can introduce ambiguity into status register results.

Following protection configuration setup (60h), an invalid command produces a lock command error (SR4 and SR5 are set to "1") in the status register. If a lock command error occurs during an ERASE SUSPEND, SR4 and SR5 are set to "1" and remain at "1" after the ERASE SUSPEND command is issued. When the ERASE

is complete, any possible error during the ERASE cannot be detected via the status register because of the previous locking command error.

A similar situation happens if an error occurs during a program operation error nested within an ERASE SUSPEND.

## CHIP PROTECTION REGISTER

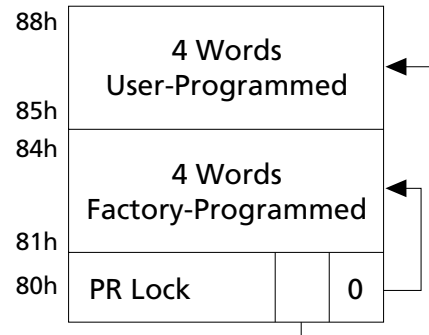

A 128-bit chip protection register can be used to fulfill the security considerations in the system (preventing device substitution).

The 128-bit security area is divided into two 64-bit segments. The first 64 bits are programmed at the manufacturing site with a unique 64-bit number. The other segment is left blank for customers to program as desired. (See Figure 12).

### READING THE CHIP PROTECTION REGISTER

The chip protection register is read in the device identification mode. To enter this mode, load the 90h command the bank containing address 00h. Once in this mode, READ cycles from addresses shown in Table 10 retrieve the specified information. To return to the read array mode, write the READ ARRAY command (FFh). The READ ARRAY command, FFh, must be issued to the bank containing address 00h prior to issuing other commands.

**Figure 12**  
**Protection Register Memory Map**

### PAGE READ MODE

The initial portion of the page mode cycle is the same as the asynchronous access cycle. Holding CE# LOW and toggling addresses A0–A2 allows random access of other words in the page.

The page size can be customized at the factory to four or eight words as required; but if no specification is made, the normal size is four words.

### ASYNCHRONOUS READ CYCLE

When accessing addresses in a random order or when switching between pages, the access time is given by  $t_{AA}$ .

When F\_CE# and F\_OE# are LOW, the data is placed on the data bus and the processor can read the data.

**Table 10**  
**Chip Configuration Addressing<sup>1</sup>**

| ITEM                          | ADDRESS <sup>2</sup> | DATA                                  |
|-------------------------------|----------------------|---------------------------------------|
| Manufacturer Code (x16)       | 00000h               | 002Ch                                 |

| Block Lock Configuration      | XX002h               | Lock<br>DQ0 = 0<br>DQ0 = 1<br>DQ1 = 1 |
| Chip Protection Register Lock | 80h                  | PR Lock                               |
| Chip Protection Register 1    | 81h–84h              | Factory Data                          |
| Chip Protection Register 2    | 85h–88h              | User Data                             |

- NOTE:**
1. Other locations within the configuration address space are reserved by Micron for future use.
  2. "XX" specifies the block address of lock configuration.

## STANDBY MODE

Icc supply current is reduced by applying a logic HIGH level on F\_CE# and F\_RP# to enter the standby mode. In the standby mode, the outputs are placed in High-Z. Applying a CMOS logic HIGH level on F\_CE# and F\_RP# reduces the current to Icc3 (MAX). If the device is deselected during an ERASE operation or during programming, the device continues to draw current until the operation is complete.

## AUTOMATIC POWER SAVE (APS) MODE

Substantial power savings are realized during periods when the Flash array is not being read and the device is in the active mode. During this time the device switches to the automatic power save (APS) mode. When the device switches to this mode, Icc is reduced to a level comparable to Icc3. Further power savings can be realized by applying a logic HIGH level on CE# to place the device in standby mode. The low level of power is maintained until another operation is initiated. In this mode, the I/Os retain the data from the last memory address read until a new address is read. This mode is entered automatically if no addresses or control signals toggle.

## DEEP POWER-DOWN MODE

By issuing an ENABLE DEEP POWER-DOWN command (see Table 3) it is possible to enable the DEEP POWER-DOWN function. In this configuration, applying a logic LOW to RST# reduces the current to Icc10, and resets all the internal registers with the exception of the individual block protection status. To exit this mode, a wait time of 100µs (tRWHDP) must elapse after a logic HIGH is applied to RST#. During the wait time, the device performs a full power-up sequence, and the power consumption may exceed the standby current limits.

## F\_VPP/F\_VCC PROGRAM AND ERASE VOLTAGES

The Flash memory devices provide in-system programming and erase with F\_VPP in the 0.9V–2.2V range. In addition to the flexible block locking, the F\_VPP programming voltage can be held LOW for absolute hardware write protection of all blocks in the Flash device. When F\_VPP is below VPPLK, any PROGRAM or ERASE operation results in an error, prompting the corresponding status register bit (SR3) to be set.

A factory option provides in-system programming and erase with F\_VPP in the 0.0V–2.2V range.

F\_VPP at 12V ±5% (F\_VPP2) is supported for a maximum of 100 cycles and 10 cumulative hours. The device can withstand 100,000 WRITE/ERASE operations when F\_VPP = F\_VCC.

During WRITE and ERASE operations, the WSM monitors the F\_VPP voltage level. WRITE/ERASE operations are allowed only when F\_VPP is within the ranges specified in Table 11.

When F\_VCC is below VLKO or F\_VPP is below VPPLK, any WRITE/ERASE operation is prevented.

## DEVICE RESET

To correctly reset the device, the RST# signal must be asserted (RST# = VIL) for a minimum of tRP. After reset, the device can be accessed for a READ operation with a delayed access time of tRWH from the rising edge of RST#. The circuitry used for generating the RST# signal needs to be common with the rest of the system reset to ensure that correct system initialization occurs. Please refer to the timing diagram for further details.

## POWER-UP SEQUENCE

The following power-up sequence is recommended to properly initialize internal chip operations:

- At power-up, RST# should be kept at VIL for 2µs after F\_VCC reaches F\_VCC (MIN).
- VCCQ should not come up before F\_VCC.
- F\_VPP should be kept at VIL to maximize data integrity.

When the power-up sequence is completed, RST# should be brought to VIH. To ensure proper power-up, the rise time of RST# (10%–90%) should be < 10µs.

**Table 11**  
**F\_VPP Ranges (V)**

| DEVICE     | MIN  | MAX  |
|------------|------|------|
| In-System  | 0.9  | 2.2  |
| In-Factory | 11.4 | 12.6 |

## FLASH ELECTRICAL SPECIFICATIONS

### ABSOLUTE MAXIMUM RATINGS\*

Voltage to Any Ball Except F\_VCC and F\_VPP  
 with Respect to Vss ..... -0.5V to +2.45V  
 F\_VPP Voltage (for BLOCK ERASE and PROGRAM  
 with Respect to Vss) ..... -0.5V to +13.5V\*\*  
 F\_VCC and VccQ Supply Voltage  
 with Respect to Vss ..... -0.3V to +2.45V  
 Output Short Circuit Current ..... 100mA  
 Operating Temperature Range ..... -40°C to +85°C  
 Storage Temperature Range ..... -55°C to +125°C  
 Soldering Cycle ..... 260°C for 10s

\*Stresses greater than those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

\*\*Maximum DC voltage on F\_VPP may overshoot to +13.5V for periods <20ns.

### RECOMMENDED OPERATING CONDITIONS

(-40°C ≤ T<sub>A</sub> ≤ +85°C)

| PARAMETER                                  | SYMBOL         | MIN    | MAX  | UNITS   | NOTES  |

## SRAM OPERATING MODES

### SRAM READ ARRAY

The operational state of the SRAM is determined by S\_CE1#, S\_CE2, S\_WE#, S\_OE#, S\_UB#, and S\_LB#, as indicated in the Truth Table. To perform an SRAM READ operation, S\_CE1#, and S\_OE#, must be at V<sub>IL</sub>, and S\_CE2 and S\_WE# must be at V<sub>IH</sub>. When in this state, S\_UB# and S\_LB# control whether the lower byte is read (S\_UB# V<sub>IH</sub>, S\_LB# V<sub>IL</sub>), the upper byte is read (S\_UB# V<sub>IL</sub>, S\_LB# V<sub>IH</sub>), both upper and lower bytes are read (S\_UB# V<sub>IL</sub>, S\_LB# V<sub>IL</sub>), or neither are read (S\_UB# V<sub>IH</sub>, S\_LB# V<sub>IH</sub>) and the device is in a standby state.

While performing an SRAM READ operation, current consumption may be reduced by reading within a 16-word page. This is done by holding S\_CE1# and

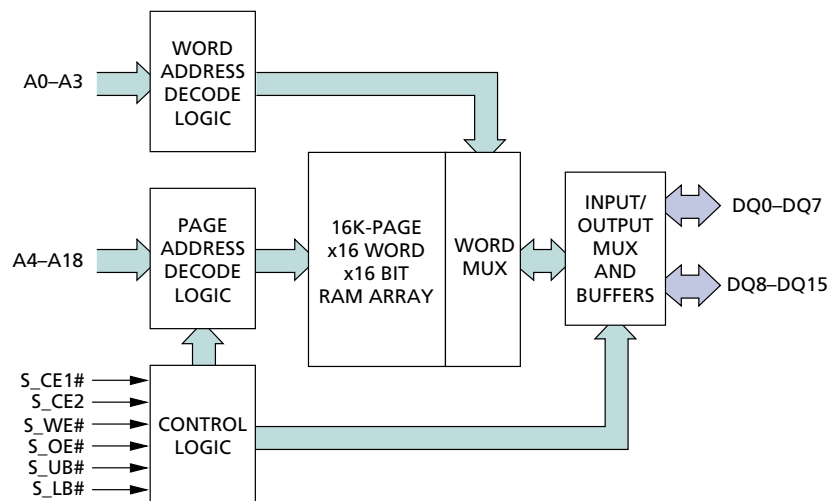

S\_OE# at V<sub>IL</sub>, S\_WE# and S\_CE2 at V<sub>IH</sub>, and toggling addresses A0–A3. S\_UB# and S\_LB# control the data width as described above.

### SRAM WRITE ARRAY

In order to perform an SRAM WRITE operation, S\_CE1# and S\_WE# must be at V<sub>IL</sub>, and S\_CE2 and S\_OE# must be at V<sub>IH</sub>. When in this state, S\_UB# and S\_LB# control whether the lower byte is written (S\_UB# V<sub>IH</sub>, S\_LB# V<sub>IL</sub>), the upper byte is written (S\_UB# V<sub>IL</sub>, S\_LB# V<sub>IH</sub>), both upper and lower bytes are written (S\_UB# V<sub>IL</sub>, S\_LB# V<sub>IL</sub>), or neither are written (S\_UB# V<sub>IH</sub>, S\_LB# V<sub>IH</sub>) and the device is in a standby state.

## 67-BALL FBGA

- NOTE:**
1. All dimensions in millimeters.
  2. Package width and length do not include mold protrusion; allowable mold protrusion is 0.27mm per side.

### DATA SHEET DESIGNATION

No Marking: This data sheet contains minimum and maximum limits specified over the complete power supply and temperature range for production devices. Although considered final, these specifications are subject to change, as further product development and data characterization sometimes occur.

**REVISION HISTORY**

|  |       |
|--|-------|
| Rev. 4 .....   | 10/02 |
| • ADVANCE designation removed.   |       |
| Rev. 3, ADVANCE .....  | 7/02  |
| • Corrected bottom boot block device address ranges                    |       |
| • Updated command descriptions   |       |
| • Updated SR5 status register bit description                          |       |
| • Updated flowcharts   |       |
| • Updated DC Characteristics   |       |
| • Corrected Status Register section                                    |       |
| • Updated the Read-While-Write/Erase Concurrency section               |       |
| • Changed $t_{RHS}$ from 200ns (MIN) to 0ns (MIN)                      |       |
| • Changed $C_{OUT}$ from 9 (TYP) and 12 (MAX) to 13 (TYP) and 15 (MAX) |       |
| Rev. 2, ADVANCE .....  | 4/02  |
| • Updated the Combined DC Characteristics table                        |       |
| • Updated $t_{AH}$ and $t_{RWH}$                                       |       |
| • Updated the chip protection mode register information                |       |
| • Updated the block locking information                                |       |
| Initial published release, ADVANCE, Rev. 1 .....                       | 1/02  |
