

# Intel<sup>®</sup> Advanced+ Boot Block Flash Memory (C3)

SCSP Family

Datasheet

## Product Features

- Flash Memory Plus SRAM
  - Reduces Memory Board Space Required, Simplifying PCB Design Complexity
- SCSP Technology
  - Smallest Memory Subsystem Footprint
  - Area : 8 x 10 mm for 16 Mbit (0.13  $\mu$ m) Flash + 2 Mbit or 4 Mbit SRAM
  - Area : 8 x 12 mm for 32 Mbit (0.13  $\mu$ m) Flash + 4 Mbit or 8 Mbit SRAM
  - Height : 1.20 mm for 16 Mbit (0.13  $\mu$ m) Flash + 2 Mbit or 4 Mbit SRAM, and 32 Mbit (0.13 $\mu$ m) Flash + 8 Mbit SRAM
  - Height : 1.40 mm for 32 Mbit (0.13  $\mu$ m) Flash + 4 Mbit SRAM
  - This Family also includes 0.25  $\mu$ m, 0.18  $\mu$ m, and 0.13  $\mu$ m technologies
- Advanced SRAM Technology
  - 70 ns Access Time
  - Low Power Operation
  - Low Voltage Data Retention Mode
- Intel<sup>®</sup> Flash Data Integrator (FDI) Software
  - Real-Time Data Storage and Code Execution in the Same Memory Device
  - Full Flash File Manager Capability
- Advanced+ Boot Block Flash Memory
  - 70 ns Access Time
  - Instant, Individual Block Locking
  - 128 bit Protection Register
  - 12 V Production Programming
  - Fast Program and Erase Suspend
  - Extended Temperature  $-25^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$
- Blocking Architecture
  - Block Sizes for Code + Data Storage
  - 4-Kword Parameter Blocks
  - 64-Kbyte Main Blocks
  - 100,000 Erase Cycles per Block
- Low Power Operation
  - Asynchronous Read Current: 9 mA (Flash)
  - Standby Current: 7  $\mu$ A (Flash)
  - Automatic Power Saving Mode
- Flash Technologies
  - 0.25  $\mu$ m ETOX<sup>™</sup> VI, 0.18  $\mu$ m ETOX<sup>™</sup> VII and 0.13  $\mu$ m ETOX<sup>™</sup> VIII Flash Technologies

The Intel<sup>®</sup> Advanced+ Boot Block Flash Memory (C3) Stacked Chip Scale Package (SCSP) device delivers a feature-rich solution for low-power applications. The C3 SCSP memory device incorporates flash memory and static RAM in one package with low voltage capability to achieve the smallest system memory solution form-factor together with high-speed, low-power operations. The C3 SCSP memory device offers a protection register and flexible block locking to enable next generation security capability. Combined with the Intel<sup>®</sup> Flash Data Integrator (Intel<sup>®</sup> FDI) software, the C3 SCSP memory device provides a cost-effective, flexible, code plus data storage solution.

## 1.0 Introduction

---

This document contains the specifications for the Intel® Advanced+ Boot Block Flash Memory (C3) Stacked Chip Scale Package (SCSP) device. C3 SCSP memory solutions are offered in the following combinations:

- 32-Mbit flash + 8-Mbit SRAM
- 32-Mbit flash + 4-Mbit SRAM
- 16-Mbit flash + 4-Mbit SRAM
- 16-Mbit flash memory + 2-Mbit SRAM

### 1.1 Document Conventions

Throughout this document, the following conventions have been adopted.

- **Voltages:**
  - 2.7 V refers to the full voltage range, 2.7 V–3.3V
  - 12 V refers to 11.4 V to 12.6 V
- **Main block(s):** 32-Kword block
- **Parameter block(s):** 4-Kword block

### 1.2 Product Overview

The C3 SCSP device combines flash memory and SRAM into a single package, which provides secure low-voltage memory solutions for portable applications.

The flash memory provides the following features:

- Enhanced security.
- Instant locking/unlocking of any flash block with zero-latency
- A 128-bit protection register that enables unique device identification, to meet the needs of next generation portable applications.
- Improved 12 V production programming for increased factory throughput.

**Table 1. Block Organization (x16)**

| Memory Device | Kwords |
|---------------|--------|
| 32-Mbit Flash | 2048   |
| 16-Mbit Flash | 1024   |
| 2-Mbit SRAM   | 128    |
| 4-Mbit SRAM   | 256    |
| 8-Mbit SRAM   | 512    |

**Note:** All words are 16 bits each.

The flash memory is asymmetrically-blocked to enable system integration of code and data storage in a single device. Each flash block can be erased independently of the others up to 100,000 times.

The flash memory has eight 8-KB parameter blocks located at either the top (denoted by -T suffix) or the bottom (-B suffix) of the address map, to accommodate different microprocessor protocols for kernel code location.

The remaining flash memory is grouped into 32-Kword main blocks.

Any individual flash memory block can be locked or unlocked instantly to provide complete protection for code or data (see [Section 5.7, “Flash Erase and Program Timings\(1\)”](#) on page 34 for details).

The flash memory contains both a Command User Interface (CUI) and a Write State Machine (WSM).

- The CUI is the interface between the microcontroller and the internal operation of the flash memory.
- The internal WSM automatically executes the algorithms and timings necessary for program and erase operations, including verification, thereby unburdening the microprocessor or microcontroller. To indicate the status of the WSM, the flash memory status register signifies block erase or word program completion and status.

Flash program and erase automation enables executing program and erase operations using an industry-standard two-write command sequence to the CUI.

- Program operations are performed in word increments.
- Erase operations erase all locations within a block simultaneously.

The system software can suspend both program and erase operations to read from any other flash block. In addition, data can be programmed to another flash block during an erase suspend.

The C3 SCSP memory device offers two low-power savings features to significantly reduce power consumption:

- Automatic Power Savings (APS) for flash memory. The C3 SCSP memory device automatically enters APS mode after a read cycle completes from the flash memory.
- Standby mode for flash and SRAM. This mode is initiated when the system deselects the device by driving F-CE# and S-CS1# or S-CS2 inactive.

To reset the flash memory, lower the F-RP# signal to GND. Setting F-RP# to GND provides CPU memory reset synchronization and additional protection against bus noise that can occur during system reset and power-up/power-down sequences.

## 1.3 Package Ballout

Figure 1. 66-Ball SCSP Package Ballout

**Notes:**

- Flash memory upgrade balls are shown up to A21 (64-Mbit flash) and A22 (128-Mbit flash). In all flash memory and SRAM combinations, 66 balls are populated on lower density devices. (Upper address balls are not populated). Ball location A10 is NC on 16/2 devices only.
- To maintain compatibility with all JEDEC Variation B options for the C6 ball location, connect this C6 land pad directly to the land pad for the G4 (A17) ball.

## 1.4 Signal Definitions

Table 2 defines the signals shown in Figure 1 “66-Ball SCSP Package Ballout” on page 8.

**Table 2. Intel® Advanced+ Boot Block SCSP Ball Descriptions (Sheet 1 of 2)**

| Symbol              | Type           | Name and Function  |
|---------------------|----------------|--|
| A[20:0]             | INPUT          | <b>ADDRESS INPUTS</b> for memory addresses. Addresses are internally latched during a program or erase cycle. <ul style="list-style-type: none"> <li>• 2-Mbit : A[16:0]</li> <li>• 4-Mbit : A[18:0]</li> <li>• 16-Mbit : A[19:0]</li> <li>• 32-Mbit A[20:0]</li> </ul>   |
| DQ[15:0]            | INPUT / OUTPUT | <b>DATA INPUTS/OUTPUTS:</b> <ul style="list-style-type: none"> <li>• Inputs array data for SRAM write operations and on the second F-CE# and F-WE# cycle during a flash program command.</li> <li>• Inputs commands to the flash memory Command User Interface when F-CE# and F-WE# are asserted.</li> <li>• Data is internally latched.</li> <li>• Outputs array, configuration, and status register data.</li> </ul> The data balls float to tristate when the chip is deselected or the outputs are disabled. |
| F-CE#               | INPUT          | <b>FLASH CHIP ENABLE:</b> Activates the flash internal control logic, input buffers, decoders, and sense amplifiers. <ul style="list-style-type: none"> <li>• F-CE# is active low.</li> <li>• F-CE# high deselects the flash memory device and reduces power consumption to standby levels.</li> </ul>   |
| S-CS <sub>1</sub> # | INPUT          | <b>SRAM CHIP SELECT1:</b> Activates the SRAM internal control logic, input buffers, decoders, and sense amplifiers. <ul style="list-style-type: none"> <li>• S-CS<sub>1</sub># is active low.</li> <li>• S-CS<sub>1</sub># high deselects the SRAM memory device and reduces power consumption to standby levels.</li> </ul>   |
| S-CS <sub>2</sub>   | INPUT          | <b>SRAM CHIP SELECT2:</b> Activates the SRAM internal control logic, input buffers, decoders, and sense amplifiers. <ul style="list-style-type: none"> <li>• S-CS<sub>2</sub> is active high.</li> <li>• S-CS<sub>2</sub> low deselects the SRAM memory device and reduces power consumption to standby levels.</li> </ul>   |
| F-OE#               | INPUT          | <b>FLASH OUTPUT ENABLE:</b> Enables flash memory outputs through the data buffers during a read operation. F-OE# is active low.  |
| S-OE#               | INPUT          | <b>SRAM OUTPUT ENABLE:</b> Enables SRAM outputs through the data buffers during a read operation. S-OE# is active low.   |
| F-WE#               | INPUT          | <b>FLASH WRITE ENABLE:</b> Controls writes to the flash memory command register and memory array. F-WE# is active low. Addresses and data are latched on the rising edge of the second F-WE# pulse.  |
| S-WE#               | INPUT          | <b>SRAM WRITE ENABLE:</b> Controls writes to the SRAM memory array. S-WE# is active low.   |
| S-UB#               | INPUT          | <b>SRAM UPPER BYTE ENABLE:</b> Enables the upper byte for SRAM (DQ <sub>8</sub> –DQ <sub>15</sub> ). S-UB# is active low.  |
| S-LB#               | INPUT          | <b>SRAM LOWER BYTE ENABLE:</b> Enables the lower byte for SRAM (DQ <sub>0</sub> –DQ <sub>7</sub> ). S-LB# is active low.   |

**Table 2. Intel® Advanced+ Boot Block SCSP Ball Descriptions (Sheet 2 of 2)**

| Symbol | Type           | Name and Function  |
|--------|----------------|--|
| F-RP#  | INPUT          | <p><b>FLASH RESET/DEEP POWER-DOWN:</b> Uses two voltage levels (<math>V_{IL}</math>, <math>V_{IH}</math>) to control reset/deep power-down mode.</p> <ul style="list-style-type: none"> <li>• <b>When F-RP# is at logic low, the device is in reset/deep power-down mode</b>, which drives the outputs to High-Z, resets the Write State Machine, and minimizes current levels (<math>I_{CCD}</math>).</li> <li>• <b>When F-RP# is at logic high, the device is in standard operation.</b></li> <li>• When F-RP# transitions from logic-low to logic-high, the device resets all blocks to locked and defaults to the read array mode.</li> </ul>  |
| F-WP#  | INPUT          | <p><b>FLASH WRITE PROTECT:</b> Controls the lock-down function of the flexible Locking feature.</p> <ul style="list-style-type: none"> <li>• <b>When F-WP# is a logic low, the lock-down mechanism is enabled</b> and blocks marked lock-down cannot be unlocked through software. After F-WP# goes low, any blocks previously marked lock-down revert to that state.</li> <li>• <b>When F-WP# is logic high, the lock-down mechanism is disabled.</b> Blocks previously locked-down are now locked, and can be unlocked or locked through software.</li> </ul> <p>See Section 7.0, “System Design Considerations” on page 41 for details on block locking.</p>  |
| F-VCC  | SUPPLY         | <b>FLASH POWER SUPPLY:</b> [2.7 V–3.3 V] Supplies power for device core operations.  |

## 2.0 Principles of Operation

The flash memory uses a CUI and automated algorithms to simplify program and erase operations. To automate program and erase operations, the WSM handles data and address latches, WE#, and system status requests.

**Figure 2. Intel® Advanced+ Boot Block SCSP Block Diagram**

### 2.1 Bus Operation

All bus cycles to or from the SCSP conform to standard microcontroller bus cycles. Four control signals dictate the data flow in and out of the flash component:

- F-CE#
- F-OE#
- F-WE#
- F-RP#

Four separate control signals handle the data flow in and out of the SRAM component:

- S-CS1#
- S-CS2
- S-OE#
- S-WE#

Table 2 on page 9 and Table 3 on page 12 summarize these bus operations .

## 2.1.1 Read

The flash memory device provides four read modes:

- Read array
- Read identifier
- Read status
- CFI query

These flash memory read modes do not depend on the  $F-V_{PP}$  voltage. Upon initial device power-up or after exit from reset, the flash memory device automatically defaults to read array mode. F-CE# and F-OE# must be asserted to obtain data from the flash memory device.

The SRAM provides only one read mode. S-CS1#, S-CS2, and S-OE# must be asserted to obtain data from the SRAM device. See Table 3 for a summary of operations.

**Table 3. Intel Advanced+ Boot Block Flash Memory SCSP Bus Operations**

|       | Modes                       | Flash Signals               |       |        |                   | SRAM Signals               |                   |        |       |                | Memory Output      |                                 | Notes |
|-------|-----------------------------|-----------------------------|-------|--------|-------------------|----------------------------|-------------------|--------|-------|----------------|--------------------|---------------------------------|-------|
|       |                             | F-RP#                       | F-CE# | F-OE1# | F-WE#             | S-CS <sub>1</sub> #        | S-CS <sub>2</sub> | S-OE1# | S-WE# | S-UB#,S-LB#(1) | Memory Bus Control | D <sub>0</sub> -D <sub>15</sub> |       |

|       | Write                       | H                           | L     | H      | L                 | SRAM must be in High Z     |                   |        |       |                | Flash              | D <sub>IN</sub>                 | 2,4   |
|       | Standby                     | H                           | H     | X      | X                 | Any SRAM mode is allowable |                   |        |       |                | Other              | High Z                          | 5,6   |
|       | Output Disable              | H                           | L     | H      | H                 | Any SRAM mode is allowable |                   |        |       |                | Other              | High Z                          | 5,6   |
|       | Reset                       | L                           | X     | X      | X                 | Any SRAM mode is allowable |                   |        |       |                | Other              | High Z                          | 5,6   |
| SRAM  | Read                        | FLASH must be in High Z     |       |        |                   | L                          | H                 | L      | H     | L              | SRAM               | D <sub>OUT</sub>                | 2,4   |
|       | Write                       | FLASH must be in High Z     |       |        |                   | L                          | H                 | H      | L     | L              | SRAM               | D <sub>IN</sub>                 | 2,4   |
|       | Standby                     | Any FLASH mode is allowable |       |        |                   | H                          | X                 | X      | X     | X              | Other              | High Z                          | 4,5,6 |
|       | Output Disable              | Any FLASH mode is allowable |       |        |                   | X                          | L                 | X      | X     | X              |                    |                                 |       |
|       | Data Retention              | Any FLASH mode is allowable |       |        |                   | L                          | H                 | H      | H     | X              | Other              | High Z                          | 4,5,6 |
|       | Any FLASH mode is allowable |                             |       |        | same as a standby |                            |                   |        |       | Other          | High Z             | 4,5,7                           |       |

**Notes:**

1. Two devices cannot drive the memory bus at the same time.
2. To place the SRAM into data retention mode, lower the S-V<sub>CC</sub> signal to the V<sub>DR</sub> range, as specified.

## 2.1.2 Output Disable

When F-OE# and S-OE# are deasserted, the SCSP output signals are placed in a high-impedance state.

### 2.1.3 Standby

When F-CE# and S-CS1# or S-CS<sub>2</sub> are deasserted, the SCSP enters a standby mode, which substantially reduces device power consumption. In standby mode, outputs are placed in a high-impedance state independent of F-OE# and S-OE#. If the flash memory device is deselected during a program or erase operation, the flash memory continues to consume active power until the program or erase operation is complete.

### 2.1.4 Flash Reset

The flash memory device enters a reset mode when RP# is driven low. In reset mode, internal circuitry is turned off and outputs are placed in a high-impedance state.

After returning from reset, a time  $t_{PHQV}$  is required until outputs are valid. A delay ( $t_{PHWL}$  or  $t_{PHEL}$ ) is required before a write sequence can be initiated. After this wake-up interval, normal operation is restored.

- The flash memory device defaults to read array mode.
- The status register is set to 80h.
- The read configuration register defaults to asynchronous reads.

If RP# is taken low during a block erase or program operation, the operation aborts and the memory contents at the aborted location are no longer valid.

### 2.1.5 Write

- Writes to flash memory occur when both F-CE# and F-WE# are asserted and F-OE# is deasserted.
- Writes to SRAM occur when both S-CS1# and S-WE# are asserted and S-OE# and S-CS<sub>2</sub> are deasserted.

Commands are written to the flash memory Command User Interface (CUI), using standard microprocessor write timings to control flash memory operations. The CUI does not occupy an addressable memory location within the flash memory device. The address and data buses are latched on the rising edge of the second F-WE# or F-CE# pulse, whichever occurs first. (See [Figure 6 on page 33](#) and [Figure 7 on page 35](#) for read and write waveforms.)

## 3.0 Flash Memory Modes of Operation

---

The flash memory has four read modes:

- Read array
- Read configuration
- Read status
- CFI query

The write modes are:

- Program
- Erase

Three additional modes are available only during suspended operations:

- Erase suspend to program
- Erase suspend to read
- Program suspend to read

These modes are reached using the commands summarized in [Table 5 “Flash Memory Command Definitions”](#) on page 19.

### 3.1 Read Array (FFh)

When F-RP# transitions from  $V_{IL}$  (reset) to  $V_{IH}$ , the flash memory device defaults to read array mode and responds to the read control inputs without additional CUI commands.

In addition, the address of the desired location must be applied to the address balls. If the flash memory device is not in read array mode, such as after a program or erase operation, the Read Array command (FFh) must be written to the CUI before array reads can take place.

### 3.2 Read Identifier (90h)

The Read Configuration mode outputs three types of information:

- Manufacturer/device identifier
- Block locking status
- Protection register

1. To switch the flash memory device to this mode, write the read configuration command (90h). In this mode, read cycles from addresses shown in [Table 4 “Read Configuration Table”](#) on [page 15](#) retrieve the specified information.
2. To return to read array mode, write the Read Array command (FFh).

**Table 4. Read Configuration Table**

| Item  | Address   | Data                | Notes |
|---|-----------|---------------------|-------|
| Manufacturer Code (x16)   | 0x00000   | 0x0089              |       |
| Device ID (See Appendix D)  | 0x00001   | ID                  |       |
| Block Lock Configuration <ul style="list-style-type: none"> <li>• Block Is Unlocked</li> <li>• Block Is Locked</li> <li>• Block Is Locked-Down</li> </ul> | 0xXX002   | LOCK                | 1, 2  |
|   |           | DQ <sub>0</sub> = 0 |       |
|   |           | DQ <sub>0</sub> = 1 |       |
| Protection Register Lock  | 0x80      | PR-LK               | 3     |
| Protection Register (x16)   | 0x81-0x88 | PR                  |       |

**Notes:**

1. See [Section 3.7](#) for valid lock status outputs.
2. "XX" specifies the block address of lock configuration being read.
3. See [Section 3.8](#) for protection register information.

Intel reserves other locations within the configuration address space for future use.

### 3.3 Read Status Register (70h)

The status register indicates the status of device operations, and the success/failure of that operation.

1. After you issue the Read Status Register (70h) command, subsequent reads output data from the status register until another command is issued.
2. To return to reading from the array, issue a Read Array (FFh) command.

The status register bits are output on DQ[7:0]. The upper byte, DQ[15:8], outputs 00h during a Read Status Register command.

The contents of the status register are latched on the falling edge of F-OE# or F-CE#, whichever occurs last. Latching on the falling edge prevents possible bus errors that might occur if status register contents change while being read. F-CE# or F-OE# must be toggled with each subsequent status read, or the status register does not indicate completion of a program or erase operation.

When the WSM is active, SR7 indicates the status of the WSM. The remaining bits in the status register indicate whether the WSM was successful in performing the desired operation (see [Table 6 "Flash Memory Status Register Definition" on page 19](#)).

### 3.3.1 Clear Status Register (50h)

The WSM sets status bits 1 through 7 to a 1 value, and clears bits 2, 6 and 7 to a 0 value. However, WSM cannot clear status bits 1 or 3 through 5 to a 0 value. Because bits 1, 3, 4, and 5 indicate various error conditions, only the Clear Status Register (50h) command can clear these bits.

If the system software controls resetting these bits, several operations (such as cumulatively programming several addresses or erasing multiple blocks in sequence) can be performed before reading the status register to determine whether an error occurred during that series.

- Clear the status register before beginning another command or sequence.
- A Read Array command must be issued before data can be read from the memory array.
- Resetting the flash memory device also clears the status register.

## 3.4 CFI Query (98h)

The CFI query mode outputs Common Flash Interface (CFI) data when the flash memory device is read.

The CFI data structure contains information such as:

- block size
  - density
  - command set
  - electrical specifications
1. To access this mode, write the CFI Query Command (98h).  
In this mode, read cycles from addresses shown in [Appendix B, “CFI Query Structure”](#) retrieve the specified information.
  2. To return to read array mode, write the Read Array command (FFh).

## 3.5 Word Program (40h/10h)

Programming uses a two-write sequence.

1. The Program Setup command (40h) is written to the CUI.
2. A second write specifies the address and data to program.
3. The WSM executes a sequence of internally timed events to program desired bits of the addressed location
4. The WSM then verifies that the bits are sufficiently programmed.

Programming the memory changes the value of specific bits within an address to 0.

*Note:* If you attempt to program a 1 value, the memory cell contents do not change and no error occurs.

The status register indicates programming status:

- While the program sequence executes, status bit 7 has a 0 value.
- To poll the status register, toggle either F-CE# or F-OE#.

While programming, the only valid commands are:

- Read Status Register
- Program Suspend
- Program Resume

1. When programming is complete, check the program status bits.
  - If the programming operation was unsuccessful, status register bit SR.4 is set to indicate a program failure.
  - If SR.3 is set, then F-V<sub>PP</sub> was not within acceptable limits, and the WSM did not execute the program command.
  - If SR.1 is set, a program operation was attempted on a locked block and the operation aborted.
2. Clear the status register before attempting the next operation.  
Any CUI instruction can follow after programming is completed.
3. To prevent inadvertent status register reads, reset the CUI to read array mode.

### 3.5.1 Suspending and Resuming Program (B0h/D0h)

The Program Suspend command halts an in-progress program operation, so that data can be read from other locations of memory.

1. After the programming process starts, write the Program Suspend command to the CUI.
  - This command requests that the WSM suspend the program sequence (at predetermined points in the program algorithm).
  - The flash memory device continues to output status register data after the Program Suspend command is written.
2. Poll status register bits SR.7 and SR.2 to determine when the program operation has been suspended (both are set to 1).

*Note:*  $t_{WHRH1}/t_{EHRH1}$  specifies the program suspend latency.

A Read Array command can be written to the CUI to read data from any block other than the suspended block. The only other valid commands, while program is suspended, are:

- Read Status Register
- Read Configuration
- CFI Query
- Program Resume.

After the Program Resume command is written to the flash memory:

- WSM continues the programming process.
- Status register bits SR.2 and SR.7 are automatically cleared.
- The flash memory device automatically outputs status register data when read (see [Appendix A, “Program/Erase Flowcharts”](#)).

*Note:* F-V<sub>PP</sub> must remain at the same F-V<sub>PP</sub> level used for program while in program suspend mode. F-RP# must also remain at V<sub>IH</sub>.

## 3.6 Block Erase (20h)

To erase a block, write the Erase Set-up and Erase Confirm commands to the CUI, along with an address identifying the block to be erased. This address is latched internally when the Erase Confirm command is issued. Block erasure results in all bits within the block being set to “1.” Only one block can be erased at a time. The WSM will execute a sequence of internally timed events to program all bits within the block to “0,” erase all bits within the block to “1,” then verify that all bits within the block are sufficiently erased. While the erase executes, status bit 7 is a “0.”

When the status register indicates that erasure is complete, check the erase status bit to verify that the erase operation was successful. If the Erase operation was unsuccessful, SR.5 of the status register will be set to a “1,” indicating an erase failure. If F-V<sub>PP</sub> was not within acceptable limits after the Erase Confirm command was issued, the WSM will not execute the erase sequence; instead, SR.5 of the status register is set to indicate an erase error, and SR.3 is set to a “1” to identify that F-V<sub>PP</sub> supply voltage was not within acceptable limits.

After an erase operation, clear the status register (50h) before attempting the next operation. Any CUI instruction can follow after erasure is completed; however, to prevent inadvertent status register reads, it is advisable to place the flash in read array mode after the erase is complete.

### 3.6.1 Suspending and Resuming Erase (B0h/D0h)

An erase operation can take several seconds to complete, therefore, the Erase Suspend command is provided to allow erase-sequence interruption in order to read data from, or program data to, another block in memory. Once an erase sequence has started, writing the Erase Suspend command to the CUI causes the device to suspend the erase sequence at a predetermined point in the erase algorithm. Block erase is suspended when Status Register bits SR[7,6] are set. Suspend latency is specified in Section 5.7, “Flash Erase and Program Timings” on page 31.

When an erase operation has been suspended, a Word Program or Read operation can be performed within any block, except the block that is in an erase suspend state. An erase operation cannot be nested within another erase suspend operation.

A suspended erase operation cannot resume until the nested program operation has completed. Read Array, Read Status Register, Clear Status Register, Read Identifier, CFI Query, Erase Resume, are all valid commands during Erase Suspend. Additionally, Program, Program Suspend, Program Resume, Lock Block, Unlock Block and Lock-Down Block are valid commands during Erase Suspend.

To resume an erase suspend operation, issue the Resume command. The Resume command can be written to any device address. When a program operation is nested within an Erase Suspend operation and the Program Suspend command is issued, the device will suspend the program

operation. When the resume command is issued, the device will resume the program operation first. Once the nested program operation is completed, an additional Resume command is required to complete the block operation.

**Table 5. Flash Memory Command Definitions**

| Command                     | Note | First Bus Cycle |         |         | Second Bus Cycle |         |      |
|-----------------------------|------|-----------------|---------|---------|------------------|---------|------|
|                             |      | Operation       | Address | Data    | Operation        | Address | Data |
| Read Array                  | 1    | Write           | X       | FFh     |                  |         |      |
| Read Identifier             | 1, 2 | Write           | X       | 90h     | Read             | IA      | ID   |
| CFI Query                   | 1, 2 | Write           | X       | 98h     | Read             | QA      | QD   |
| Read Status Register        | 1    | Write           | X       | 70h     | Read             | X       | SRD  |
| Clear Status Register       | 1    | Write           | X       | 50h     |                  |         |      |
| Word Program                | 1, 3 | Write           | X       | 40h/10h | Write            | PA      | PD   |
| Block Erase/Confirm         | 1    | Write           | X       | 20h     | Write            | BA      | D0h  |
| Program/Erase Suspend       | 1    | Write           | X       | B0h     |                  |         |      |
| Program/Erase Resume        | 1    | Write           | X       | D0h     |                  |         |      |
| Lock Block                  | 1    | Write           | X       | 60h     | Write            | BA      | 01h  |
| Unlock Block                | 1, 4 | Write           | X       | 60h     | Write            | BA      | D0h  |
| Lock-Down Block             | 1    | Write           | X       | 60h     | Write            | BA      | 2Fh  |
| Protection Register Program | 1    | Write           | X       | C0h     | Write            | PA      | PD   |
| Lock Protection Register    | 1    | Write           | X       | C0h     | Write            | PA      | FFFD |

X = Don't Care      PA = Program Address    BA = Block Address    IA = Identifier Address    QA = Query Address

SRD = Status Register Data    PD = Program Data      ID = Identifier Data      QD = Query Data

**Notes:**

1. When writing commands, the upper data bus [DQ<sub>8</sub>–DQ<sub>15</sub>] should be either V<sub>IL</sub> or V<sub>IH</sub>, to minimize current draw.
2. Following the Read Configuration or CFI Query commands, read operations output device configuration or CFI query information, respectively.
3. Either 40h or 10h command is valid, but the Intel standard is 40h.
4. When unlocking a block, WP# must be held for three clock cycles (1 clock cycle after the second command bus cycle).

**Table 6. Flash Memory Status Register Definition**

| WSMS | ESS | ES | PS | VPPS | PSS | BLS | R |
|------|-----|----|----|------|-----|-----|---|
| 7    | 6   | 5  | 4  | 3    | 2   | 1   | 0 |

| Bit Number  | NOTES:   |
|---|--|
| SR.7 WRITE STATE MACHINE STATUS<br>1 = Ready (WSMS)<br>0 = Busy   | Check Write State Machine bit first to determine Word Program or Block Erase completion, before checking Program or Erase Status bits.   |
| SR.6 = ERASE-SUSPEND STATUS (ESS)<br>1 = Erase Suspended<br>0 = Erase In Progress/Completed                                     | When Erase Suspend is issued, WSM halts execution and sets both WSMS and ESS bits to 1. ESS bit remains set to 1 until an Erase Resume command is issued.  |
| SR.5 = ERASE STATUS (ES)<br>1 = Error In Block Erase<br>0 = Successful Block Erase  | When this bit is set to 1, WSM has applied the max. number of erase pulses and is still unable to verify successful block erasure.   |
| SR.4 = PROGRAM STATUS (PS)<br>1 = Error in Programming<br>0 = Successful Programming  | When this bit is set to 1, WSM has attempted but failed to program a word/byte.  |
| SR.3 = F-V <sub>PP</sub> STATUS (VPPS)<br>1 = F-V <sub>PP</sub> Low Detect, Operation Abort<br>0 = F-V <sub>PP</sub> OK         | The F-V <sub>PP</sub> status bit does not provide continuous indication of V <sub>PP</sub> level. The WSM interrogates F-V <sub>PP</sub> level only after the Program or Erase command sequences have been entered, and informs the system if F-V <sub>PP</sub> has not been switched on. The F-V <sub>PP</sub> is also checked before the operation is verified by the WSM. The F-V <sub>PP</sub> status bit is not guaranteed to report accurate feedback between V <sub>PP</sub> and V <sub>PP1 min</sub> . |
| SR.2 = PROGRAM SUSPEND STATUS (PSS)<br>1 = Program Suspended<br>0 = Program in Progress/Completed                               | When Program Suspend is issued, WSM halts execution and sets both WSMS and PSS bits to 1. PSS bit remains set to 1 until a Program Resume command is issued.   |
| SR.1 = BLOCK LOCK STATUS<br>1 = Prog/Erase attempted on a locked block; Operation aborted.<br>0 = No operation to locked blocks | If a program or erase operation is attempted to one of the locked blocks, this bit is set by the WSM. The operation specified is aborted and the device is returned to read status mode.   |
| SR.0 = RESERVED FOR FUTURE ENHANCEMENTS (R)   | This bit is reserved for future use and should be masked out when polling the status register.   |

**Note:** A Command Sequence Error is indicated when SR.4, SR.5 and SR.7 are set.

### 3.7 Block Locking

The instant, individual block locking feature that allows any flash block to be locked or unlocked with no latency, which enables instant code and data protection.

This locking offers two levels of protection. The first level allows software-only control of block locking (useful for data blocks that change frequently), while the second level requires hardware interaction before locking can be changed (useful for code blocks that change infrequently).

The following sections will discuss the operation of the locking system. The term “state [XYZ]” will be used to specify locking states; e.g., “state [001],” where X = value of WP#, Y = bit DQ<sub>1</sub> of the Block Lock status register, and Z = bit DQ<sub>0</sub> of the Block Lock status register. [Table 8 “Block Locking State Transitions” on page 23](#) defines all of these possible locking states.

### 3.7.1 Block Locking Operation Summary

The following concisely summarizes the locking functionality.

All blocks are locked when powered-up, and can be unlocked or locked with the Unlock and Lock commands.

- The Lock-Down command locks a block and prevents it from being unlocked when WP# = 0.
- When WP# = 1, Lock-Down is overridden and commands can unlock/lock locked-down blocks.
- When WP# returns to 0, locked-down blocks return to Lock-Down.
- Lock-Down is cleared only when the device is reset or powered-down.

The locking status of each block can set to Locked, Unlocked, and Lock-Down, each of which will be described in the following sections. A comprehensive state table for the locking functions is shown in [Table 8 on page 23](#), and a flowchart for locking operations is shown in [Figure 19 on page 50](#).

### 3.7.2 Locked State

The default status of all blocks upon power-up or reset is locked (states [001] or [101]). Locked blocks are fully protected from alteration. Any program or erase operations attempted on a locked block will return an error on bit SR.1 of the status register. The status of a locked block can be changed to Unlocked or Lock-Down using the appropriate software commands. Unlocked blocks can be locked issuing the “Lock” command sequence, 60h followed by 01h.

### 3.7.3 Unlocked State

Unlocked blocks (states [000], [100], [110]) can be programmed or erased. All unlocked blocks return to the Locked state when the device is reset or powered down. The status of an unlocked block can be changed to Locked or Locked-Down using the appropriate software commands. A Locked block can be unlocked by writing the Unlock command sequence, 60h followed by D0h.

### 3.7.4 Lock-Down State

Blocks that are Locked-Down (state [011]) are protected from program and erase operations (just like Locked blocks), but their protection status cannot be changed using software commands alone. A Locked or Unlocked block can be Locked-down by writing the Lock-Down command sequence, 60h followed by 2Fh. Locked-Down blocks revert to the Locked state when the device is reset or powered down.

The Lock-Down function is dependent on the WP# input ball. When WP# = 0, blocks in Lock-Down [011] are protected from program, erase, and lock status changes. When WP# = 1, the Lock-Down function is disabled ([111]) and locked-down blocks can be individually unlocked by software command to the [110] state, where they can be erased and programmed. These blocks can then be re-locked [111] and unlocked [110] as desired while WP# remains high. When WP# goes low, blocks that were previously locked-down return to the Lock-Down state [011] regardless of any changes made while WP# was high. Device reset or power-down resets all blocks, including those in Lock-Down, to Locked state.

### 3.7.5 Reading Lock Status for a Block

The lock status of every block can be read in the configuration read mode of the device. To enter this mode, write 90h to the device. Subsequent reads at Block Address + 00002 will output the lock status of that block. The lock status is represented by the least significant outputs, DQ<sub>0</sub> and DQ<sub>1</sub>. DQ<sub>0</sub> indicates the Block Lock/Unlock status and is set by the Lock command and cleared by the Unlock command. It is also automatically set when entering Lock-Down. DQ<sub>1</sub> indicates Lock-Down status and is set by the Lock-Down command. It cannot be cleared by software, only by device reset or power-down.

**Table 7. Block Lock Status**

| Item                     | Address | Data                |
|--------------------------|---------|---------------------|
| Block Lock Configuration | XX002   | LOCK                |
| • Block Is Unlocked      |         | DQ <sub>0</sub> = 0 |
| • Block Is Locked        |         | DQ <sub>0</sub> = 1 |
| • Block Is Locked-Down   |         | DQ <sub>1</sub> = 1 |

### 3.7.6 Locking Operation During Erase Suspend

Changes to block lock status can be performed during an erase suspend by using the standard locking command sequences to unlock, lock, or lock-down a block. This is useful in the case when another block needs to be updated while an erase operation is in progress.

To change block locking during an erase operation, first write the erase suspend command (B0h), then check the status register until it indicates that the erase operation has been suspended. Next write the desired lock command sequence to a block and the lock status will be changed. After completing any desired lock, read, or program operations, resume the erase operation with the Erase Resume command (D0h).

If a block is locked or locked-down during a suspended erase of the same block, the locking status bits will be changed immediately, but when the erase is resumed, the erase operation will complete.

Locking operations cannot be performed during a program suspend.

### 3.7.7 Status Register Error Checking

Using nested locking or program command sequences during erase suspend can introduce ambiguity into status register results.

Since locking changes are performed using a two cycle command sequence, e.g., 60h followed by 01h to lock a block, following the Configuration Setup command (60h) with an invalid command will produce a lock command error (SR.4 and SR.5 will be set to 1) in the status register. If a lock command error occurs during an erase suspend, SR.4 and SR.5 will be set to 1, and will remain at 1 after the erase is resumed. When erase is complete, any possible error during the erase cannot be detected via the status register because of the previous locking command error.

A similar situation happens if an error occurs during a program operation error nested within an erase suspend.

**Table 8. Block Locking State Transitions**

| Current State |                 |                 |                           | Erase/<br>Program<br>Allowed? | Next State after Command Input |             |             |
|---------------|-----------------|-----------------|---------------------------|-------------------------------|--------------------------------|-------------|-------------|
| WP#           | DQ <sub>1</sub> | DQ <sub>0</sub> | Name                      |                               | Lock                           | Unlock      | Lock-Down   |
| 0             | 0               | 0               | Unlocked                  | Yes                           | Go To [001]                    | –           | Go To [011] |
| 1             | 0               | 0               | Unlocked                  | Yes                           | Go To [101]                    | –           | Go To [111] |
| 0             | 0               | 1               | Locked ( <b>Default</b> ) | No                            | –                              | Go To [000] | Go To [011] |
| 1             | 0               | 1               | Locked                    | No                            | –                              | Go To [100] | Go To [111] |
| 0             | 1               | 1               | Locked-Down               | No                            | –                              | –           | –           |
| 1             | 1               | 0               | Lock-Down                 | Yes                           | Go To [111]                    | –           | Go To [111] |
| 1             | 1               | 1               | Disabled                  | No                            | –                              | Go To [110] | –           |

**Notes:**

1. “–” indicates no change in the current state.
2. In this table, the notation [XYZ] denotes the locking state of a block, where X = WP#, Y = DQ<sub>1</sub>, and Z = DQ<sub>0</sub>. The current locking state of a block is defined by the state of WP# and the two bits of the block lock status (DQ<sub>0</sub>, DQ<sub>1</sub>). DQ<sub>0</sub> indicates if a block is locked (1) or unlocked (0). DQ<sub>1</sub> indicates if a block has been locked-down (1) or not (0).
3. At power-up or device reset, all blocks default to Locked state [001] (if WP# = 0). holding WP# = 0 is the recommended default.
4. The “Erase/Program Allowed?” column shows whether erase and program operations are enabled (Yes) or disabled (No) in that block’s current locking state.
5. The “Lock Command Input Result [Next State]” column shows the result of writing the three locking commands (Lock, Unlock, Lock-Down) in the current locking state. For example, “Goes To [001]” would mean that writing the command to a block in the current locking state would change it to [001].
6. The 128 bits of the protection register are divided into two 64-bit segments. One of the segments is programmed at the Intel factory with a unique 64 bit number, which is unchangeable. The other segment is left blank for customer designs to program as desired. Once the customer segment is programmed, it can be locked to prevent reprogramming.

## 3.8 128 Bit Protection Register

The C3 SCSP architecture includes a 128-bit protection register than can be used to increase the security of a system design. For example, the number contained in the protection register can be used to “mate” the flash component with other system components such as the CPU or ASIC, preventing device substitution.

### 3.8.1 Reading the Protection Register

The protection register is read in the configuration read mode. The device is switched to this mode by writing the Read Configuration command (90h). Once in this mode, read cycles from addresses shown in Appendix E retrieve the specified information. To return to read array mode, write the Read Array command (FFh).

### 3.8.2 Programming the Protection Register (C0h)

The protection register bits are programmed using the two-cycle Protection Program command. The 64-bit number is programmed 16 bits at a time for word-wide parts. First write the Protection Program Setup command, C0h. The next write to the device will latch in address and data and program the specified location. The allowable addresses are shown in Appendix E. See [Figure 20](#) “Protection Register Programming Flowchart” on page 51.

Any attempt to address Protection Program commands outside the defined protection register address space will result in a status register error (program error bit SR.4 will be set to 1). Attempting to program or to a previously locked protection register segment will result in a status register error (program error bit SR.4 and lock error bit SR.1 will be set to 1).

### 3.8.3 Locking the Protection Register

The user-programmable segment of the protection register is lockable by programming Bit 1 of the PR-LOCK location to 0. Bit 0 of this location is programmed to 0 at the Intel factory to protect the unique device number. This bit is set using the Protection Program command to program FFFDh to the PR-LOCK location. After these bits have been programmed, no further changes can be made to the values stored in the protection register. A Protection Program command to locked words will result in a status register error (program error bit SR.4 and Lock Error bit SR.1 will be set to 1). The protection register lockout state is not reversible.

**Figure 3. Protection Register Memory Map**

## 4.0 Power and Reset Considerations

---

### 4.1 Power-Up/Down Characteristics

In order to prevent any condition that may result in a spurious write or erase operation, it is recommended to power-up F-VCC, F-VCCQ and S-VCC together. Conversely, F-VCC, F-VCCQ and S-VCC must power-down together. It is also recommended to power-up F-VPP with or slightly after F-VCC. Conversely, F-VPP must power down with or slightly before F-VCC.

If F-VCCQ and/or F-VPP are not connected to the F-VCC supply, then F-VCC should attain F-VCCMin before applying F-VCCQ and F-VPP. Device inputs should not be driven before supply voltage = F-VCCMin. Power supply transitions should only occur when F-RP# is low.

### 4.2 Additional Flash Features

C3 SCSP products provide in-system programming and erase in the 1.65 V–3.3 V range. For fast production programming, it also includes a low-cost, backward-compatible 12 V programming feature.

#### 4.2.1 Improved 12 Volt Production Programming

When F-V<sub>PP</sub> is between 1.65 V and 3.3 V, all program and erase current is drawn through the F-V<sub>CC</sub> signal. Note that if F-V<sub>PP</sub> is driven by a logic signal, V<sub>IH</sub> min = 1.65 V. That is, F-V<sub>PP</sub> must remain above 1.65 V to perform in-system flash modifications. When F-V<sub>PP</sub> is connected to a 12 V power supply, the device draws program and erase current directly from the F-V<sub>PP</sub> signal. This eliminates the need for an external switching transistor to control the voltage F-V<sub>PP</sub>. [Figure 12 “Example Power Supply Configurations” on page 43](#) shows examples of how the flash power supplies can be configured for various usage models.

The 12 V F-V<sub>PP</sub> mode enhances programming performance during the short period of time typically found in manufacturing processes; however, it is not intended for extended use. 12 V may be applied to F-V<sub>PP</sub> during program and erase operations for a maximum of 1000 cycles on the main blocks and 2500 cycles on the parameter blocks. F-V<sub>PP</sub> may be connected to 12 V for a total of 80 hours maximum. Stressing the device beyond these limits may cause permanent damage.

#### 4.2.2 F-V<sub>PP</sub> ≤ V<sub>PPLK</sub> for Complete Protection

In addition to the flexible block locking, the F-V<sub>PP</sub> programming voltage can be held low for absolute hardware write protection of all blocks in the flash device. When F-V<sub>PP</sub> is below V<sub>PPLK</sub>, any program or erase operation will result in an error, prompting the corresponding status register bit (SR.3) to be set.

## 5.0 Electrical Specifications

### 5.1 Absolute Maximum Ratings

**Warning:** Stressing the device beyond the Absolute Maximum Ratings in [Table 9](#) might cause permanent damage. These are stress ratings only. Do not operate the flash memory device beyond the Operating Conditions in [Table 10](#). Extended exposure beyond these Operating Conditions might affect device reliability.

**NOTICE:** This datasheet contains information on products in full production. The specifications are subject to change without notice. Verify with your local Intel Sales office that you have the latest datasheet before finalizing a design.

**Table 9. Absolute Maximum Ratings**

| Parameter   | Maximum Rating    | Notes |
|---|-------------------|-------|
| Extended Operating Temperature  | -25°C to +85°C    |       |
| During Read   |                   |       |
| During Flash Block Erase and Program  |                   |       |
| Temperature under Bias  |                   |       |
| Storage Temperature   | -65°C to +125°C   |       |
| Voltage on Any Ball (except F-VCC / F-VCCQ / S-VCC and F-VPP) with Respect to GND             | -0.5 V to +3.3 V  | 1     |
| F-V <sub>PP</sub> Voltage (for Block Erase and Program) with Respect to GND                   | -0.5 V to +13.5 V | 1,2,4 |
| F-V <sub>CC</sub> / F-V <sub>CCQ</sub> / S-V <sub>CC</sub> Supply Voltage with Respect to GND | -0.2V to +3.3 V   |       |
| Output Short Circuit Current  | 100 mA            | 3     |

**Notes:**

- Minimum DC voltage is -0.5 V on input/output balls. During transitions, this level may undershoot to -2.0 V for periods < 20 ns. Maximum DC voltage on input/output balls is F-V<sub>CC</sub> / F-V<sub>CCQ</sub> / S-V<sub>CC</sub> + 0.5 V which, during transitions, may overshoot to F-V<sub>CC</sub> / F-V<sub>CCQ</sub> / S-V<sub>CC</sub> + 2.0 V for periods < 20 ns.
- Maximum DC voltage on F-V<sub>PP</sub> may overshoot to +14.0 V for periods < 20 ns.
- F-V<sub>PP</sub> voltage is normally 1.65 V–3.3 V. Connection to supply of 11.4 V–12.6 V can only be done for 1000 cycles on the main blocks and 2500 cycles on the parameter blocks during program/erase. F-V<sub>PP</sub> may be connected to 12 V for a total of 80 hours maximum. See [Section 4.2.1](#) for details
- Output shorted for no more than one second. No more than one output shorted at a time.

## 5.2 Operating Conditions

**Table 10. Maximum Operating Conditions**

| Symbol                             | Parameter   | Notes | Min     | Max  | Units  |
|------------------------------------|---|-------|---------|------|--------|
| T <sub>CASE</sub>                  | Operating Temperature   |       | -25     | +85  | °C     |
| V <sub>CC</sub> / V <sub>CCQ</sub> | F-V <sub>CC</sub> / F-V <sub>CCQ</sub> / S-V <sub>CC</sub> Supply Voltage | 1     | 2.7     | 3.3  | Volts  |
| V <sub>PP1</sub>                   | Supply Voltage  | 1     | 1.65    | 3.3  | Volts  |
| V <sub>PP2</sub>                   |   | 1, 2  | 11.4    | 12.6 | Volts  |
| Cycling                            | Block Erase Cycling   | 2     | 100,000 |      | Cycles |

**Notes:**

1. F-V<sub>CC</sub>/F-V<sub>CCQ</sub> must share the same supply. F-V<sub>CC</sub>/S-V<sub>CC</sub> must share the same supply when not in data retention.
2. Applying F-V<sub>PP</sub> = 11.4 V–12.6 V during a program/erase can only be done for a maximum of 1000 cycles on the main blocks and 2500 cycles on the parameter blocks. F-V<sub>PP</sub> may be connected to 12 V for a total of 80 hours maximum. See [Section 4.2.1](#) for details.

## 5.3 Capacitance

T<sub>CASE</sub> = +25°C, f = 1 MHz

**Table 11. Capacitance**

| Sym              | Parameter          | Notes | Typ | Max | Units | Conditions             |
|------------------|--------------------|-------|-----|-----|-------|------------------------|
| C <sub>IN</sub>  | Input Capacitance  | 1     | 16  | 18  | pF    | V <sub>IN</sub> = 0 V  |
| C <sub>OUT</sub> | Output Capacitance | 1     | 20  | 22  | pF    | V <sub>OUT</sub> = 0 V |

**Note:** Sampled, not 100% tested.

## 5.4 DC Characteristics

Table 12. DC Characteristics (Sheet 1 of 2)

| Symbol    | Parameter   | Device                                       | Note | 2.7 V – 3.3 V |          | Unit    | Test Conditions   |  |
|-----------|---|--|------|---------------|----------|---------|---|--|
|           |   |  |      | Typ           | Max      |         |   |  |
| $I_{LI}$  | Input Load Current  | Flash/<br>SRAM                               | 1    |               | $\pm 2$  | $\mu A$ | F- $V_{CC}$ /S- $V_{CC} = V_{CC}$ Max<br>$V_{IN} = V_{CC}$ Max or GND   |  |
| $I_{LO}$  | Output Leakage Current                                      | Flash/<br>SRAM                               | 1    | 0.2           | $\pm 10$ | $\mu A$ | F- $V_{CC}$ /S- $V_{CC} = V_{CC}$ Max<br>$V_{IN} = V_{CC}$ Max or GND   |  |

**Notes:**

1. All currents are in RMS unless otherwise noted. Typical values at nominal F-V<sub>CC</sub>/S-V<sub>CC</sub>; T<sub>CASE</sub> = +25 °C.
2. Automatic Power Savings (APS) reduces I<sub>CCR</sub> to approximately standby levels in static operation (CMOS inputs).
3. Sampled, not 100% tested.
4. I<sub>CCES</sub> and I<sub>CCWS</sub> are specified with device de-selected. If device is read while in erase suspend, current draw is sum of I<sub>CCES</sub> and I<sub>CCR</sub>. If the device is read while in program suspend, current draw is the sum of I<sub>CCWS</sub> and I<sub>CCR</sub>.

Table 13. DC Characteristics

| Symbol     | Parameter                          | Device         | Note | 2.7 V – 3.3 V  |                | Units | Test Conditions  |
|------------|------------------------------------|----------------|------|----------------|----------------|-------|--|
|            |                                    |                |      | Min            | Max            |       |  |
| $V_{IL}$   | Input Low Voltage                  | Flash/<br>SRAM |      | -0.2           | 0.6            | V     |  |
| $V_{IH}$   | Input High Voltage                 | Flash/<br>SRAM |      | 2.3            | $V_{CC} + 0.2$ | V     |  |
| $V_{OL}$   | Output Low Voltage                 | Flash/<br>SRAM |      | -0.10          | 0.10           | V     | F- $V_{CC}$ /S- $V_{CC} = V_{CC}$ Min<br>$I_{OL} = 100 \mu A$  |
| $V_{OH}$   | Output High Voltage                | Flash/<br>SRAM |      | $V_{CC} - 0.1$ |                | V     | F- $V_{CC}$ /S- $V_{CC} = V_{CC}$ Min<br>$I_{OH} = -100 \mu A$ |
| $V_{PPLK}$ | F- $V_{PP}$ Lock-Out Voltage       | Flash          | 1    |                | 1.0            | V     | Complete Write Protection                                      |
| $V_{PP1}$  | F- $V_{PP}$ during Program / Erase | Flash          | 1    | 1.65           | 3.3            | V     |  |
| $V_{PP2}$  | Operations                         |                | 1,2  | 11.4           | 12.6           |       |  |
| $V_{LKO}$  | $V_{CC}$ Prog/Erase Lock Voltage   | Flash          |      | 1.5            |                | V     |  |
| $V_{LKO2}$ | $V_{CCQ}$ Prog/Erase Lock Voltage  | Flash          |      | 1.2            |                | V     |  |

**Notes:**

1. Erase and Program are inhibited when F- $V_{pp} < V_{PPLK}$  and not guaranteed outside the valid F- $V_{pp}$  ranges of  $V_{PP1}$  and  $V_{PP2}$ .
2. Applying F- $V_{pp} = 11.4V-12.6V$  during program/erase can only be done for a maximum of 1000 cycles on the main blocks and 2500 cycles on the parameter blocks. F- $V_{pp}$  may be connected to 12 V for a total of 80 hours maximum. See [Section 4.2.1](#) for details.

Figure 4. Input/Output Reference Waveform

**Note:** AC test inputs are driven at  $V_{CCQ}$  for a logic "1" and 0.0V for a logic "0." Input timing begins, and output timing ends, at  $V_{CCQ}/2$ . Input rise and fall times (10%–90%) <10 ns. Worst case speed conditions are when  $V_{CCQ} = V_{CCQMin}$ .

Figure 5. Test Configuration

**Note:**  $C_L$  includes jig capacitance.

Flash Test Configuration Component Values Table

| Test Configuration        | C <sub>L</sub> (pF) |
|---------------------------|---------------------|
| 2.7 V–3.3 V Standard Test | 50                  |

## 5.5 Flash AC Characteristics.

Table 14. Flash AC Characteristics—Read Operations

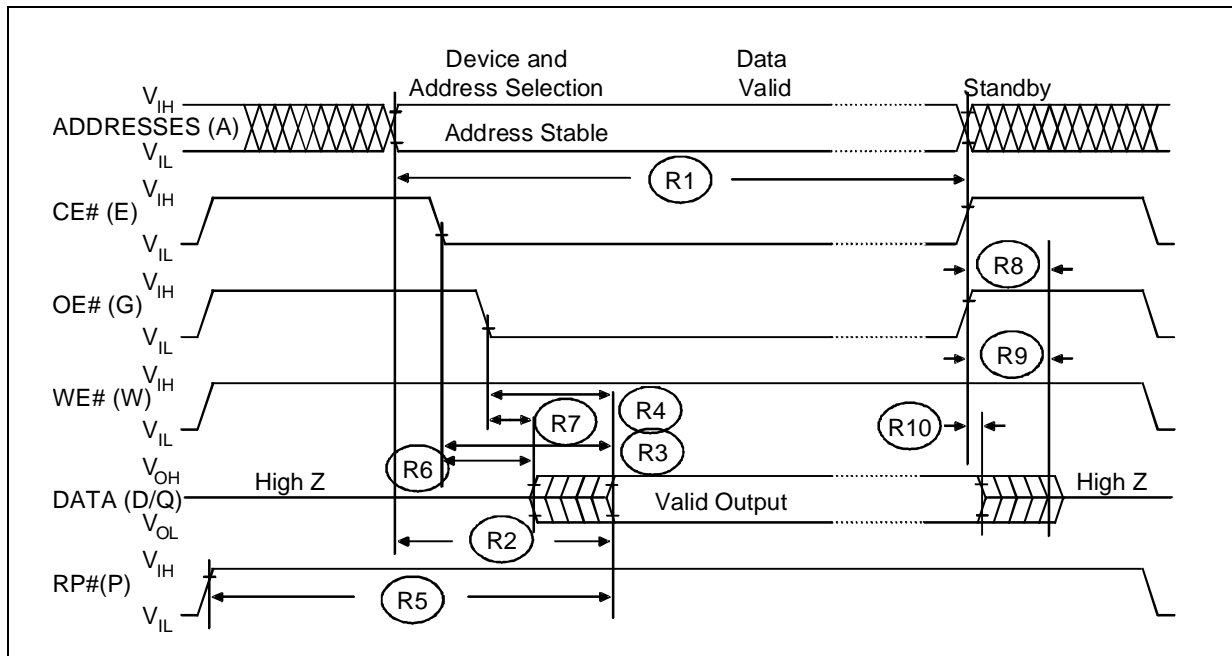

| #    | Sym        | Parameter   | Density       | 16-Mbit       |     |     |     |      |     | 32-Mbit |     |     |     | Unit |

| R5   | $t_{PHQV}$ | F-RP# to Output Delay   |               |               | 150 |     | 150 |      | 150 |         | 150 |     | 150 | ns   |
| R6   | $t_{ELQX}$ | F-CE# to Output in Low Z  | 2             | 0             |     | 0   |     | 0    |     | 0       |     | 0   |     | ns   |
| R7   | $t_{GLQX}$ | F-OE# to Output in Low Z  | 2             | 0             |     | 0   |     | 0    |     | 0       |     | 0   |     | ns   |
| R8   | $t_{EHQZ}$ | F-CE# to Output in High Z   | 2             |               | 20  |     | 25  |      | 25  |         | 20  |     | 20  | ns   |
| R9   | $t_{GHQZ}$ | F-OE# to Output in High Z   | 2             |               | 20  |     | 20  |      | 20  |         | 20  |     | 20  | ns   |
| R10  | $t_{OH}$   | Output Hold from Address F-CE#, or F-OE# Change, Whichever Occurs First | 2             | 0             |     | 0   |     | 0    |     | 0       |     | 0   |     | ns   |

**Notes:**

1. F-OE# may be delayed up to  $t_{ELQV} - t_{GLQV}$  after the falling edge of CE# without impact on  $t_{ELQV}$ .
2. Sampled, but not 100% tested.
3. See Figure 6 "AC Waveform: Flash Read Operations" on page 33.
4. See Figure 4, "Input/Output Reference Waveform" on page 28 for timing measurements and maximum allowable input slew rate.

Figure 6. AC Waveform: Flash Read Operations

## 5.6 Flash AC Characteristics—Write Operations

Table 15. Flash AC Characteristics—Write Operations (Sheet 2 of 2)

| #    | Sym                   | Parameter                                     | Density       | 16-Mbit       |     |      | 32-Mbit |     | Unit |
|------|-----------------------|---|---------------|---------------|-----|------|---------|-----|------|
|      |                       |   | Product       | -70           | -90 | -110 | -70     | -90 |      |
|      |                       |   | Voltage Range | 2.7 V - 3.3 V |     |      |         |     |      |
| Note | Min                   | Min   | Min           | Min           | Min |      |         |     |      |
| W10  | $t_{VPWH}$ $t_{VPEH}$ | F- $V_{PP}$ Setup to F-WE# (F-CE#) Going High | 3             | 200           | 200 | 200  | 200     | 200 | ns   |
| W11  | $t_{QVVL}$            | F- $V_{PP}$ Hold from Valid SRD               | 3             | 0             | 0   | 0    | 0       | 0   | ns   |

**Notes:**

- Write pulse width ( $t_{WP}$ ) is defined from F-CE# or F-WE# going low (whichever goes low last) to F-CE# or F-WE# going high (whichever goes high first). Hence,  $t_{WP} = t_{WLWH} = t_{ELEH} = t_{WLEH} = t_{ELWH}$ . Similarly, write pulse width high ( $t_{WPH}$ ) is defined from F-CE# or F-WE# going high (whichever goes high first) to F-CE# or F-WE# going low (whichever goes low first). Hence,  $t_{WPH} = t_{WHWL} = t_{EHEL} = t_{WHEL} = t_{EHWL}$ .
- Refer to Table 5 “Flash Memory Command Definitions” on page 19 for valid  $A_{IN}$  or  $D_{IN}$ .
- Sampled, but not 100% tested.

See Figure 4 “Input/Output Reference Waveform” on page 30 for timing measurements and maximum allowable input slew rate.

See Figure 7 “AC Waveform: Flash Program and Erase Operations” on page 35.

## 5.7 Flash Erase and Program Timings<sup>(1)</sup>

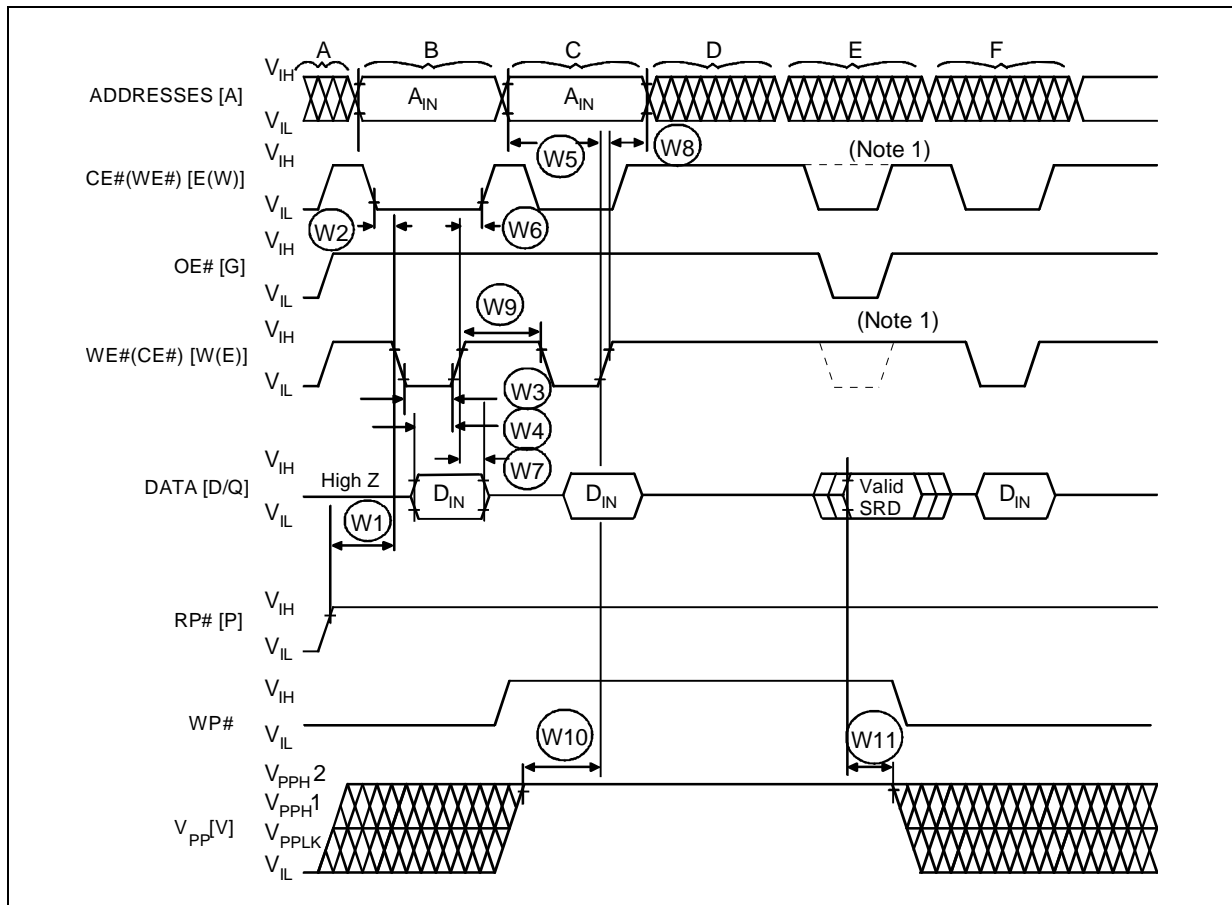

Table 16. Flash Erase and Program Timings

| Symbol                  | Parameter                                       | F- $V_{PP}$ | 1.65 V– 3.3 V      |      | 11.4 V– 12.6 V     |      | Unit    |
|-------------------------|---|-------------|--------------------|------|--------------------|------|---------|
|                         |   | Note        | Typ <sup>(1)</sup> | Max  | Typ <sup>(1)</sup> | Max  |         |

|                         | 0.13 $\mu$ m and 0.18 $\mu$ m Word Program Time | 2, 3        | 12                 | 200  | 8                  | 185  |         |
| $t_{WHQV2} / t_{EHQV2}$ | 4-KW Parameter Block Erase Time (Word)          | 2, 3        | 0.5                | 4    | 0.4                | 4    | s       |
| $t_{WHQV3} / t_{EHQV3}$ | 32-KW Main Block Erase Time (Word)              | 2, 3        | 1                  | 5    | 0.6                | 5    | s       |
| $t_{WHRH1} / t_{EHRH1}$ | Program Suspend Latency                         | 3           | 5                  | 10   | 5                  | 10   | $\mu$ s |
| $t_{WHRH2} / t_{EHRH2}$ | Erase Suspend Latency                           | 3           | 5                  | 20   | 5                  | 20   | $\mu$ s |

**Notes:**

- Typical values measured at  $T_{CASE} = +25$  °C and nominal voltages.
- Excludes external system-level overhead.
- Sampled, but not 100% tested.

Figure 7. AC Waveform: Flash Program and Erase Operations

**Notes:**

1. F-CE# must be toggled low when reading Status Register Data. F-WE# must be inactive (high) when reading Status Register Data.
2. F-VCC Power-Up and Standby.
3. Write Program or Erase Setup Command.
4. Write Valid Address and Data (for Program) or Erase Confirm Command.
5. Automated Program or Erase Delay.
6. Read Status Register Data (SRD): reflects completed program/erase operation.
7. Write Read Array Command.

## 5.8 Flash Reset Operations

Figure 8. AC Waveform: Reset Operation

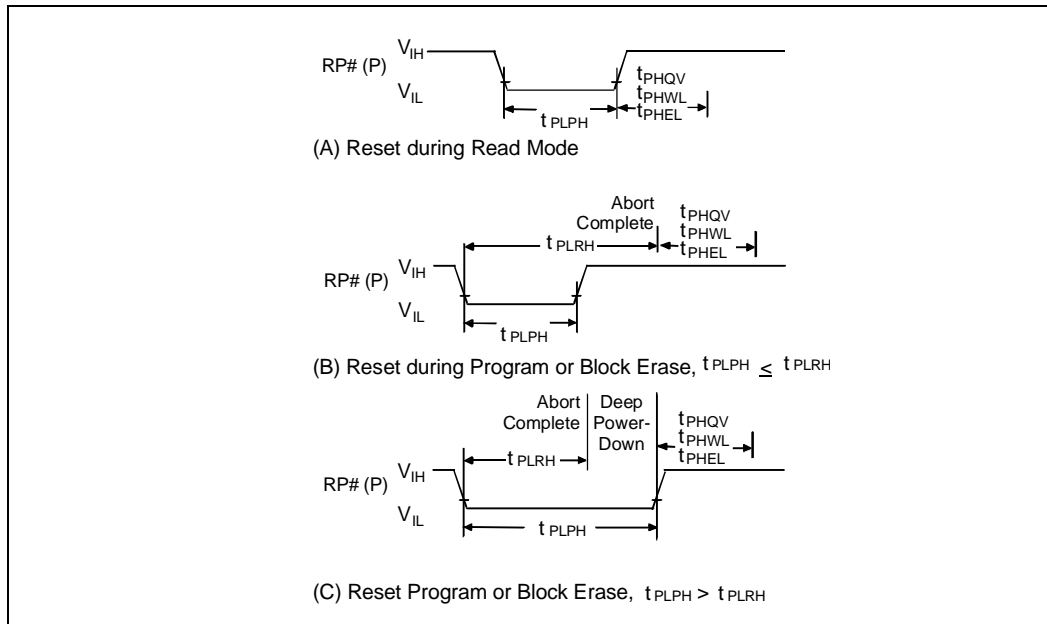

Table 17. Reset Specifications<sup>(1)</sup>

| Symbol             | Parameter   | Note | F-V <sub>CC</sub> 2.7 V – 3.3 V |     | Unit |
|--------------------|---|------|---------------------------------|-----|------|
|                    |   |      | Min                             | Max |      |
| t <sub>PLPH</sub>  | F-RP# Low to Reset during Read (If F-RP# is tied to V <sub>CC</sub> , this specification is not applicable) | 2,4  | 100                             |     | ns   |
| t <sub>PLRH1</sub> | F-RP# Low to Reset during Block Erase   | 3,4  |                                 | 22  | μs   |
| t <sub>PLRH2</sub> | F-RP# Low to Reset during Program   | 3,4  |                                 | 12  | μs   |

**Notes:**

1. See Section 2.1.4, "Flash Reset" on page 13 for a full description of these conditions.
2. If t<sub>PLPH</sub> is < 100 ns the device may still reset but this is not guaranteed.
3. If F-RP# is asserted while a block erase or word program operation is not executing, the reset will complete within 100 ns.
4. Sampled, but not 100% tested.

## 5.9 SRAM AC Characteristics—Read Operations

Table 18. SRAM AC Characteristics—Read Operations<sup>(1)</sup>

| #   | Sym                | Parameter  | Density       | 2/4/8-Mbit   |     | Unit |
|-----|--------------------|--|---------------|--------------|-----|------|
|     |                    |  | Voltage Range | 2.7 V– 3.3 V |     |      |
|     |                    |  | Note          | Min          | Max |      |
| R1  | $t_{RC}$           | Read Cycle Time  |               | 70           | –   | ns   |
| R2  | $t_{AA}$           | Address to Output Delay  |               | –            | 70  | ns   |
| R3  | $t_{CO1}, t_{CO2}$ | S-CS1#, S-CS2 to Output Delay  |               | –            | 70  | ns   |
| R4  | $t_{OE}$           | S-OE# to Output Delay  |               | –            | 35  | ns   |
| R5  | $t_{BA}$           | S-UB#, LB# to Output Delay   |               | –            | 70  | ns   |
| R6  | $t_{LZ1}, t_{LZ2}$ | S-CS1#, S-CS2 to Output in Low Z   | 2,3           | 5            | –   | ns   |
| R7  | $t_{OLZ}$          | S-OE# to Output in Low Z   | 3             | 0            | –   | ns   |
| R8  | $t_{HZ1}, t_{HZ2}$ | S-CS1#, S-CS2 to Output in High Z  | 2,3,4         | 0            | 25  | ns   |
| R9  | $t_{OHZ}$          | S-OE# to Output in High Z  | 3,4           | 0            | 25  | ns   |
| R10 | $t_{OH}$           | Output Hold from Address, S-CS1#, S-CS2, or S-OE# Change, Whichever Occurs First |               | 0            | –   | ns   |
| R11 | $t_{BLZ}$          | S-UB#, S-LB# to Output in Low Z  | 3             | 0            | –   | ns   |
| R12 | $t_{BHZ}$          | S-UB#, S-LB# to Output in High Z   | 3             | 0            | 25  | ns   |

**Note:**

1. See Figure 9 “AC Waveform: SRAM Read Operations” on page 38.
2. At any given temperature and voltage condition,  $t_{HZ}$  (Max) is less than and  $t_{LZ}$  (Max) both for a given device and from device to device interconnection.
3. Sampled, but not 100% tested.
4. Timings of  $t_{HZ}$  and  $t_{OHZ}$  are defined as the time at which the outputs achieve the open circuit conditions and are not referenced to output voltage levels.

Figure 9. AC Waveform: SRAM Read Operations

## 5.10 SRAM AC Characteristics—Write Operations

Table 19. SRAM AC Characteristics—Write Operations<sup>(1,2)</sup>

| #  | Sym             | Parameter   | Density    |               | Unit |   |    |
|----|-----------------|---|------------|---------------|------|---|----|
|    |                 |   | 2/4/8-Mbit |               |      |   |    |
|    |                 |   | Volt       | 2.7 V – 3.3 V |      |   |    |
|    |                 |   | Note       | Min           | Max  |   |    |
| W1 | t <sub>WC</sub> | Write Cycle Time  |            |               | 70   | – | ns |
| W2 | t <sub>AS</sub> | Address Setup to S-WE# (S-CS <sub>1</sub> #) and S-UB#, S-LB# Going Low | 3          |               | 0    | – | ns |
| W3 | t <sub>WP</sub> | S-WE# (S-CS <sub>1</sub> #) Pulse Width                                 | 4          |               | 55   | – | ns |
| W4 | t <sub>DW</sub> | Data to Write Time Overlap  |            |               | 30   | – | ns |
| W5 | t <sub>AW</sub> | Address Setup to S-WE# (S-CS <sub>1</sub> #) Going High                 |            |               | 60   | – | ns |
| W6 | t <sub>CW</sub> | S-CE# (S-WE#) Setup to S-WE# (S-CS <sub>1</sub> #) Going High           |            |               | 60   | – | ns |
| W7 | t <sub>DH</sub> | Data Hold Time from S-WE# (S-CS <sub>1</sub> #) High                    |            |               | 0    | – | ns |

Table 19. SRAM AC Characteristics—Write Operations<sup>(1,2)</sup>

| #  | Sym             | Parameter  | Density |     | 2/4/8-Mbit |       | Unit |
|----|-----------------|--|---------|-----|------------|-------|------|
|    |                 |  | Volt    |     | 2.7 V      | 3.3 V |      |
|    |                 |  | Note    | Min | Max        |       |      |
| W8 | t <sub>WR</sub> | Write Recovery   | 5       | 0   | –          | ns    |      |
| W9 | t <sub>BW</sub> | S-UB#, S-LB# Setup to S-WE# (S-CS <sub>1</sub> #) Going High |         | 60  | –          | ns    |      |

**Notes:**

1. See [Figure 10 “AC Waveform: SRAM Write Operations” on page 39](#).
2. A write occurs during the overlap (t<sub>WP</sub>) of low S-CS<sub>1</sub># and low S-WE#. A write begins when S-CS<sub>1</sub># goes low and S-WE# goes low with asserting S-UB# or S-LB# for single byte operation or simultaneously asserting S-UB# and S-LB# for double byte operation. A write ends at the earliest transition when S-CS<sub>1</sub># goes high and S-WE# goes high. The t<sub>WP</sub> is measured from the beginning of write to the end of write.
3. t<sub>AS</sub> is measured from the address valid to the beginning of write.
4. t<sub>WP</sub> is measured from S-CS<sub>1</sub># going low to end of write.
5. t<sub>WR</sub> is measured from the end of write to the address change. t<sub>WR</sub> applied in case a write ends as S-CS<sub>1</sub># or S-WE# going high.

Figure 10. AC Waveform: SRAM Write Operations

## 5.11 SRAM Data Retention Characteristics—Extended Temperature

Table 20. SRAM Data Retention Characteristics<sup>(1)</sup>—Extended Temperature

| Sym       | Parameter                       | Note | Min      | Typ | Max | Unit          | Test Conditions   |
|-----------|---------------------------------|------|----------|-----|-----|---------------|---|
| $V_{DR}$  | S- $V_{CC}$ for Data Retention  |      | 1.5      | —   | 3.3 | V             | $CS_1\# \geq V_{CC} - 0.2\text{ V}$                               |
| $I_{DR}$  | Deep Retention Current - 8-Mbit | 2    | —        | —   | 6   | $\mu\text{A}$ | S- $V_{CC} = 1.5\text{ V}$<br>$CS_1\# \geq V_{CC} - 0.2\text{ V}$ |
|           | Deep Retention Current - 4-Mbit |      | —        | —   | 5   | $\mu\text{A}$ |   |
|           | Deep Retention Current - 2-Mbit |      | —        | —   | 4   | $\mu\text{A}$ |   |
| $t_{SDR}$ | Data Retention Set-up Time      |      | 0        | —   | —   | ns            | See Data Retention Waveform                                       |
| $t_{RDR}$ | Recovery Time                   |      | $t_{RC}$ | —   | —   | ns            |   |

**Notes:**

1. Typical values at nominal S- $V_{CC}$ ,  $T_{CASE} = +25\text{ }^\circ\text{C}$ .
2. S- $CS_1\# \geq V_{CC} - 0.2\text{ V}$ , S- $CS_2 \geq V_{CC} - 0.2\text{ V}$  (S- $CS_1\#$  controlled) or S- $CS_2 \leq 0.2\text{ V}$  (S- $CS_2$  controlled).

Figure 11. SRAM Data Retention Waveform

## 6.0 Migration Guide Information

---

Typically, it is important to discuss footprint migration compatibility between a new product and existing products. In this specific case, the SCSP allows the system designer to remove two separate memory footprints for individual flash and SRAM and replace them with a single footprint, thus resulting in an overall reduction in board space required. This implies that a new printed circuit board would be used to take advantage of this feature.

Since the flash in SCSP shares the same features as the C3 features, conversions from the C3 are described in *AP-658 Designing for Upgrade to the Advanced+ Boot Block Flash Memory*, order number 292216.

Please contact your local Intel representation for detailed information about specific Flash + SRAM system migrations.

## 7.0 System Design Considerations

---

This section contains information that would have been contained in a product design guide in earlier generations. In an effort to simplify the amount of documentation, relevant system design considerations have been combined into this document.

### 7.1 Background

The C3 SCSP combines the features of the C3 flash memory architecture with a low-power SRAM to achieve an overall reduction in system board space. This enables applications to integrate security with simple software and hardware configurations, while also combining the system SRAM and flash into one common footprint. This section discusses how to take full advantage of the C3 SCSP.

#### 7.1.1 Flash + SRAM Footprint Integration

The SCSP memory solution can be used to replace a subset of the memory subsystem within a design. Where a previous design may have used two separate footprints for SRAM and Flash, you can now replace with the industry-standard I-ballout of the SCSP device. This allows for an overall reduction in board space, which allows the design to integrate both the flash and the SRAM into one component.

## 7.1.2 C3 Flash Memory Features

C3 adds the following new features to Intel Advanced Boot Block architecture:

- Instant, individual block locking provides software/hardware controlled, independent locking/unlocking of any block with zero latency to protect code and data.
- A 128-bit Protection Register enables system security implementations.
- Improved 12 V production programming simplifies the system configuration required to implement 12 V fast programming.
- Common Flash Interface (CFI) provides component information on the chip to allow software-independent device upgrades.

For more information on specific advantages of the C3, please see *AP-658 Designing with the Advanced+ Boot Block Flash Memory Architecture*.

## 7.2 Flash Control Considerations

The flash device is protected against accidental block erasure or programming during power transitions. Power supply sequencing is not required, since the device is indifferent as to which power supply, F-VPP or F-VCC, powers-up first. Example flash power supply configurations are shown in [Figure 12 “Example Power Supply Configurations”](#) on page 43.

### 7.2.1 F-RP# Connected to System Reset

The use of F-RP# during system reset is important with automated program/erase devices since the system expects to read from the flash memory when it comes out of reset. If a CPU reset occurs without a flash memory reset, proper CPU initialization will not occur because the flash memory may be providing status information instead of array data. Intel recommends connecting F-RP# to the system CPU RESET# signal to allow proper CPU/flash initialization following system reset.

System designers must guard against spurious writes when F-V<sub>CC</sub> voltages are above V<sub>LKO</sub>. Since both F-WE# and F-CE# must be low for a command write, driving either signal to V<sub>IH</sub> will inhibit writes to the device. The CUI architecture provides additional protection since alteration of memory contents can only occur after successful completion of the two-step command sequences. The device is also disabled until F-RP# is brought to V<sub>IH</sub>, regardless of the state of its control inputs.

By holding the device in reset (F-RP# connected to system PowerGood) during power-up/down, invalid bus conditions during power-up can be masked, providing yet another level of memory protection.

### 7.2.2 F-V<sub>CC</sub>, F-V<sub>PP</sub> and F-RP# Transition

The CUI latches commands as issued by system software and is not altered by F-V<sub>PP</sub> or F-CE# transitions or WSM actions. Its default state upon power-up, after exit from reset mode or after F-V<sub>CC</sub> transitions above V<sub>LKO</sub> (Lockout voltage), is read array mode.

After any program or block erase operation is complete (even after F-V<sub>PP</sub> transitions down to V<sub>PPLK</sub>), the CUI must be reset to read array mode via the Read Array command if access to the flash memory array is desired.

**Figure 12. Example Power Supply Configurations**

**Note:** 1. A resistor can be used if the F- $V_{CC}$  supply can sink adequate current based on resistor value.

### 7.3 Noise Reduction

SCSP memory’s power switching characteristics require careful device decoupling. System designers should consider three supply current issues for both the flash and SRAM:

- Standby current levels ( $I_{CCS}$ )
- Read current levels ( $I_{CCR}$ )
- Transient peaks produced by falling and rising edges of F-CE#, S-CS1#, and S-CS2.

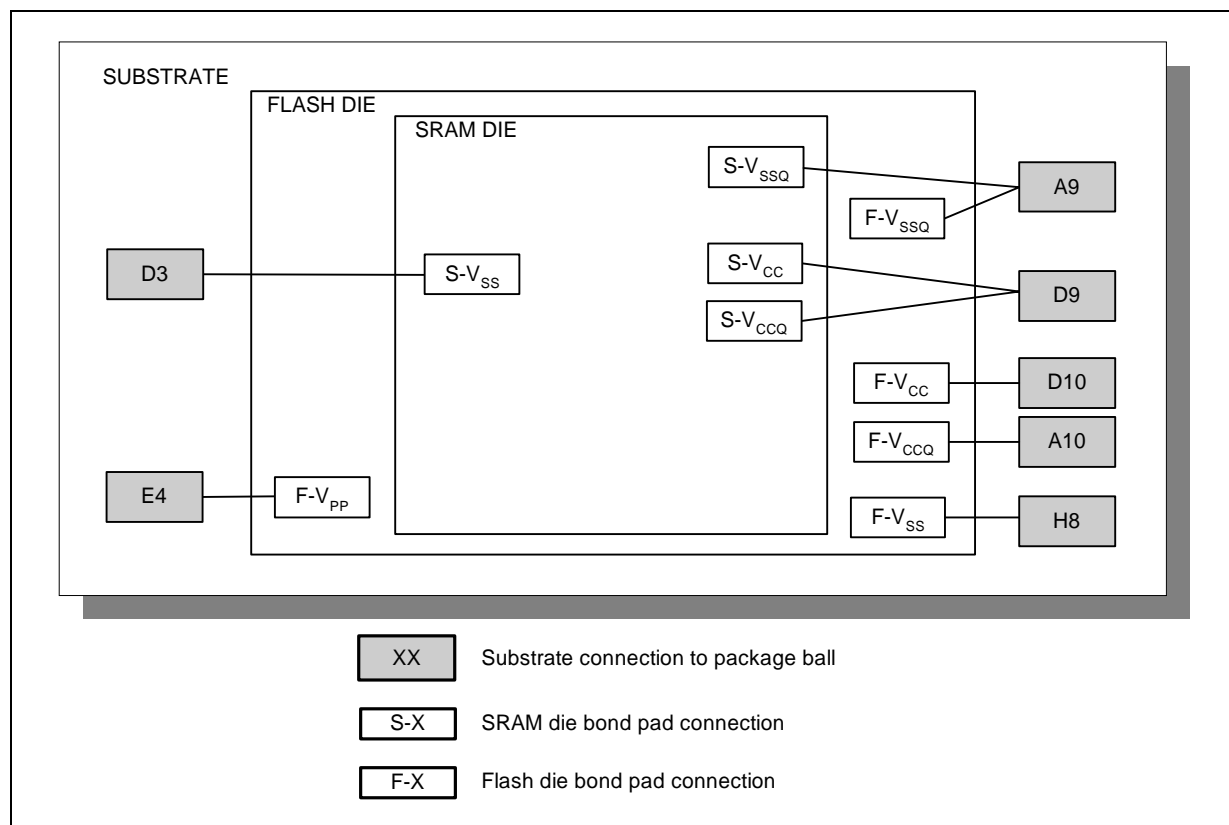

Transient current magnitudes depend on the device outputs’ capacitive and inductive loading. Two-line control and proper decoupling capacitor selection will suppress these transient voltage peaks. Each device should have a capacitors between individual power (F-VCC, F-VCCQ, F-VPP, S-VCC) and ground (GND) signals. High-frequency, inherently low-inductance capacitors should be placed as close as possible to the package leads.

Noise issues within a system can cause devices to operate erratically if it is not adequately filtered. In order to avoid any noise interaction issues within a system, it is recommended that the design contain the appropriate number of decoupling capacitors in the system. Noise issues can also be reduced if leads to the device are kept very short, in order to reduce inductance.

Decoupling capacitors between  $V_{CC}$  and  $V_{SS}$  reduce voltage spikes by supplying the extra current needed during switching. Placing these capacitors as close to the device as possible reduces line inductance. The capacitors should be low inductance capacitors; surface mount capacitors typically exhibit lower inductance.

It is highly recommended that systems use a 0.1  $\mu\text{f}$  capacitor for each of the D9, D10, A10 and E4 grid ballout locations (see Figure 1 “66-Ball SCSP Package Ballout” on page 8 for ballout). These capacitors are necessary to avoid undesired conditions created by excess noise. Smaller capacitors can be used to decouple higher frequencies.

Figure 13. Typical Flash + SRAM Substrate Power and Ground Connections

**Notes:**

1. Substrate connections refer to ballout locations shown in [Figure 1 "66-Ball SCSP Package Ballout"](#) on [page 8](#).
2. 0.1  $\mu$ f capacitors should be used with D9, D10, A10 and E4.
3. Some SRAM devices do not have a S-VSSQ; in this case, this pad is a S-VSS.
4. Some SRAM devices do not have a S-VSSQ; in this case, this pad is a VCC.

## 7.4 Simultaneous Operation

The term simultaneous operation is used to describe the ability to read or write to the SRAM while also programming or erasing flash. In addition, F-CE#, S-CS1# and S-CS2 should not be enabled at the same time. (See [Table 2 "Intel® Advanced+ Boot Block SCSP Ball Descriptions"](#) on [page 9](#) for a summary of recommended operating modes.) Simultaneous operation of the can be summarized by the following:

- SRAM read/write are during a Flash Program or Erase Operation are allowed.
- Simultaneous Bus Operations between the Flash and SRAM are **not** allowed (because of bus contention).

### 7.4.1 SRAM Operation during Flash “Busy”

This functionality provides the ability to use both the flash and the SRAM “at the same time” within a system, similar to the operation of two devices with separate footprints. This operation can be achieved by following the appropriate timing constraints within a system.

### 7.4.2 Simultaneous Bus Operations

Operations that require both the SRAM and Flash to be in active mode are disallowed. An example of these cases would include simultaneous reads on both the flash and SRAM, which would result in contention for the data bus. Finally, a read of one device while attempting to write to the other (similar to the conditions of direct memory access (DMA) operation) are also not within the recommended operating conditions. Basically, only one memory can drive the outputs out the device at one given point in time.

## 7.5 Printed Circuit Board Notes

The Intel SCSP will save significant space on your PCB by combining two chips into one BGA style package. Intel SCSP has a 0.8 mm pitch that can be routed on your Printed Circuit Board with conventional design rules. Trace widths of 0.127 mm (0.005 inches) are typical. Unused balls in the center of the package are not populated to further increase the routing options. Standard surface mount process and equipment can be used for the Intel SCSP.

Figure 14. Standard PCB Design Rules Can be Used with SCSP Device

Note: Top View

## 7.6 System Design Notes Summary

The C3 SCSP allows higher levels of memory component integration. Different power supply configurations can be used within the system to achieve different objectives. At least three different 0.1 µf capacitors should be used to decouple the devices within a system. SRAM reads or writes during a flash program or erase are supported operations. Standard printed circuit board technology can be used.

## Appendix B CFI Query Structure

This appendix defines the data structure or “database” returned by the Common Flash Interface (CFI) Query command. System software should parse this structure to gain critical information such as block size, density, x8/x16, and electrical specifications. Once this information has been obtained, the software will know which command sets to use to enable flash writes, block erases, and otherwise control the flash component. The Query is part of an overall specification for multiple command set and control interface descriptions called Common Flash Interface, or CFI.

### B.1 Query Structure Output

The Query “database” allows system software to gain information for controlling the flash component. This section describes the device’s CFI-compliant interface that allows the host system to access Query data.

Query data are always presented on the lowest-order data outputs (DQ<sub>0-7</sub>) only. The numerical offset value is the address relative to the maximum bus width supported by the device. On this family of devices, the Query table device starting address is a 10h, which is a word address for x16 devices.

For a word-wide (x16) device, the first two bytes of the Query structure, “Q” and “R” in ASCII, appear on the low byte at word addresses 10h and 11h. This CFI-compliant device outputs 00h data on upper bytes. Thus, the device outputs ASCII “Q” in the low byte (DQ<sub>0-7</sub>) and 00h in the high byte (DQ<sub>8-15</sub>).

At Query addresses containing two or more bytes of information, the least significant data byte is presented at the lower address, and the most significant data byte is presented at the higher address.

In all of the following tables, addresses and data are represented in hexadecimal notation, so the “h” suffix has been dropped. In addition, since the upper byte of word-wide devices is always “00h,” the leading “00” has been dropped from the table notation and only the lower byte value is shown. Any x16 device outputs can be assumed to have 00h on the upper byte in this mode.

**Table 21. Summary of Query Structure Output as a Function of Device and Mode**

| Device         | Hex Offset | Code | ASCII Value |
|----------------|------------|------|-------------|
| Device Address | 10:        | 51   | “Q”         |
|                | 11:        | 52   | “R”         |
|                | 12:        | 59   | “Y”         |

**Table 22. Example of Query Structure Output of x16 and x8 Devices**

| Word Addressing                 |                                 |           | Byte Addressing                |                                |          |
|---------------------------------|---------------------------------|-----------|--------------------------------|--------------------------------|----------|
| Offset                          | Hex Code                        | Value     | Offset                         | Hex Code                       | Value    |
| A <sub>15</sub> -A <sub>0</sub> | D <sub>15</sub> -D <sub>0</sub> |           | A <sub>7</sub> -A <sub>0</sub> | D <sub>7</sub> -D <sub>0</sub> |          |
| 0010h                           | 0051                            | “Q”       | 10h                            | 51                             | “Q”      |
| 0011h                           | 0052                            | “R”       | 11h                            | 52                             | “R”      |
| 0012h                           | 0059                            | “Y”       | 12h                            | 59                             | “Y”      |
| 0013h                           | P_IDLO                          | PrVendor  | 13h                            | P_IDLO                         | PrVendor |
| 0014h                           | P_IDHI                          | ID #      | 14h                            | P_IDLO                         | ID #     |
| 0015h                           | PLO                             | PrVendor  | 15h                            | P_IDHI                         | ID #     |
| 0016h                           | PHI                             | TblAdr    | 16h                            | ...                            | ...      |
| 0017h                           | A_IDLO                          | AltVendor | 17h                            |                                |          |
| 0018h                           | A_IDHI                          | ID #      | 18h                            |                                |          |
| ...                             | ...                             | ...       | ...                            |                                |          |

## B.2 Query Structure Overview

The Query command causes the flash component to display the Common Flash Interface (CFI) Query structure or “database.” The structure sub-sections and address locations are summarized below.

**Table 23. Query Structure**

| Offset  | Sub-Section Name                            | Description  | Notes |
|---------|---|--|-------|
| 00h     |   | Manufacturer Code  | 1     |
| 01h     |   | Device Code  | 1     |
| (BA+2)h | Block Status Register                       | Block-specific information   | 1,2   |
| 04-0Fh  | Reserved                                    | Reserved for vendor-specific information                                       | 1     |
| 10h     | CFI Query Identification String             | Command set ID and vendor data offset  | 1     |
| 1Bh     | System Interface Information                | Device timing & voltage information  | 1     |
| 27h     | Device Geometry Definition                  | Flash device layout  | 1     |
| P       | Primary Intel-Specific Extended Query Table | Vendor-defined additional information specific to the Primary Vendor Algorithm | 1,3   |

**Notes:**

1. Refer to the Query Structure Output section and offset 28h for the detailed definition of offset address as a function of device bus width and mode.
2. BA = The beginning location of a Block Address (e.g., 08000h is the beginning location of block 1 when the block size is 32 Kword).
3. Offset 15 defines “P” which points to the Primary Intel-specific Extended Query Table.

## B.3 Block Lock Status Register

The Block Status Register indicates whether an erase operation completed successfully or whether a given block is locked or can be accessed for flash program/erase operations.

Block Erase Status (BSR.1) allows system software to determine the success of the last block erase operation. BSR.1 can be used just after power-up to verify that the  $V_{CC}$  supply was not accidentally removed during an erase operation. This bit is only reset by issuing another erase operation to the block. The Block Status Register is accessed from word address 02h within each block.

**Table 24. Block Status Register**

| Offset  | Length | Description  | Address | Value           | Notes |
|---------|--------|--|---------|-----------------|-------|
| (BA+2)h | 1      | Block Lock Status Register   | BA+2:   | --00 or --01    | 1     |
|         |        | BSR.0 Block Lock Status<br>0 = Unlocked<br>1 = Locked                  | BA+2:   | (bit 0): 0 or 1 |       |
|         |        | BSR.1 Block Lock-Down Status<br>0 = Not locked down<br>1 = Locked down | BA+2:   | (bit 1): 0 or 1 |       |
|         |        | BSR 2–7: <i>Reserved for future use</i>                                | BA+2:   | (bit 2–7): 0    |       |

**Note:** 1. BA = The beginning location of a Block Address (i.e., 008000h is the beginning location of block 1 in word mode.)

## B.4 CFI Query Identification String

The Identification String provides verification that the component supports the Common Flash Interface specification. It also indicates the specification version and supported vendor-specified command set(s).

**Table 25. CFI Identification**

| Offset | Length | Description   | Addr.             | Hex Code             | Value             |
|--------|--------|---|-------------------|----------------------|-------------------|
| 10h    | 3      | Query-unique ASCII string "QRY"   | 10:<br>11:<br>12: | --51<br>--52<br>--59 | "Q"<br>"R"<br>"Y" |
| 13h    | 2      | Primary vendor command set and control interface ID code.<br>16-bit ID code for vendor-specified algorithms           | 13:<br>14:        | --03<br>--00         |                   |
| 15h    | 2      | Extended Query Table primary algorithm address  | 15:<br>16:        | --35<br>--00         |                   |
| 17h    | 2      | Alternate vendor command set and control interface ID code<br>0000h means no second vendor-specified algorithm exists | 17:<br>18:        | --00<br>--00         |                   |
| 19h    | 2      | Secondary algorithm Extended Query Table address.<br>0000h means none exists  | 19:<br>1A:        | --00<br>--00         |                   |

## B.5 System Interface Information

**Table 26. System Interface Information**

| Offset | Length | Description   | Addr. | Hex Code | Value  |
|--------|--------|---|-------|----------|--------|
| 1Bh    | 1      | V <sub>CC</sub> logic supply minimum program/erase voltage<br>bits 0–3 BCD 100 mV<br>bits 4–7 BCD volts         | 1B:   | --27     | 2.7 V  |

## B.7 Intel-Specific Extended Query Table

Certain flash features and commands are optional. The Intel-Specific Extended Query table specifies this and other similar types of information.

**Table 28. Primary-Vendor Specific Extended Query (Sheet 1 of 2)**

| Offset <sup>(1)</sup><br>P = 35h | Length | Description<br>(Optional Flash Features and Commands)   | Addr. | Hex Code  | Value |
|----------------------------------|--------|---|-------|-----------|-------|
| (P+0)h                           | 3      | Primary extended query table  | 35:   | --50      | "P"   |
| (P+1)h                           |        | Unique ASCII string "PRI"   | 36:   | --52      | "R"   |
| (P+2)h                           |        |   | 37:   | --49      | "I"   |
| (P+3)h                           | 1      | Major version number, ASCII   | 38:   | --31      | "1"   |
| (P+4)h                           | 1      | Minor version number, ASCII   | 39:   | --30      | "0"   |
| (P+5)h                           | 4      | Optional feature and command support (1=yes, 0=no)<br><br>bits 9–31 are reserved; undefined bits are "0." If bit 31 is "1" then another 31 bit field of optional features follows at the end of the bit-30 field.<br><br>bit 0 Chip erase supported<br>bit 1 Suspend erase supported<br>bit 2 Suspend program supported<br>bit 3 Legacy lock/unlock supported | 3A:   | --66      |       |
| (P+6)h                           |        |   | 3B:   | --00      |       |
| (P+7)h                           |        |   | 3C:   | --00      |       |

## Appendix D Device ID Table

Table 33. Device ID

| Read Configuration Address and Data |     |         |      |
|-------------------------------------|-----|---------|------|
| Item                                |     | Address | Data |
| Manufacturer Code                   | x16 | 00000   | 0089 |
| Device Code                         |     |         |      |
| 16-Mbit x 16-T                      | x16 | 00001   | 88C2 |
| 16-Mbit x 16-B                      | x16 | 00001   | 88C3 |
| 32-Mbit x 16-T                      | x16 | 00001   | 88C4 |
| 32-Mbit x 16-B                      | x16 | 00001   | 88C5 |

**Note:** Other locations within the configuration address space are reserved by Intel for future use.

## Appendix E Protection Register Addressing

**Table 34. Protection Register Addressing**

| Word-Wide Protection Register Addressing |         |    |    |    |    |    |    |    |    |
|--|---------|----|----|----|----|----|----|----|----|
| Word                                     | Use     | A7 | A6 | A5 | A4 | A3 | A2 | A1 | A0 |
| LOCK                                     | Both    | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0  | Factory | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 1  |
| 1  | Factory | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 0  |
| 2  | Factory | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 1  |
| 3  | Factory | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  |
| 4  | User    | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 1  |
| 5  | User    | 1  | 0  | 0  | 0  | 0  | 1  | 1  | 0  |
| 6  | User    | 1  | 0  | 0  | 0  | 0  | 1  | 1  | 1  |
| 7  | User    | 1  | 0  | 0  | 0  | 1  | 0  | 0  | 0  |

**Note:** All address lines not specified in the above table must be 0 when accessing the Protection Register—for example, A<sub>21</sub>–A<sub>8</sub> = 0.

## Appendix F Mechanical and Shipping Media Details

### F.8 Mechanical Specification

**Note:** Shaded pins indicate upper address balls for 64-Mbit and 128-Mbit devices. In all Flash and SRAM combinations, 66 balls are populated on lower density devices. (Upper address balls are not populated).

**Table 35. Packaging Specifications (0.18µm and 0.25µm) (Sheet 1 of 2)**

|   | Sym | Millimeters |        |        | Inches |        |        |
