Table 7: Pin Descriptions

Symbol	Type	Description
ODT0, ODT1	Input (SSTL_18)	**On-die termination:** ODT (registered HIGH) enables termination resistance internal to the DDR2 SDRAM. When enabled, ODT is only applied to the following pins: DQ, DQS, DQS#, and CB. The ODT input will be ignored if disabled via the LOAD MODE command.
CK0, CK0#	Input (SSTL_18)	**Clock:** CK and CK# are differential clock inputs. All address and control input signals are sampled on the crossing of the positive edge of CK and negative edge of CK#. Output data (DQs and DQS/DQS#) is referenced to the crossings of CK and CK#.
CKE0, CKE1	Input (SSTL_18)	**Clock enable:** CKE (registered HIGH) activates and CKE (registered LOW) deactivates clocking circuitry on the DDR2 SDRAM.
S0#, S1#	Input (SSTL_18)	**Chip select:** S# enables (registered LOW) and disables (registered HIGH) the command decoder.
RAS#, CAS#, WE#	Input (SSTL_18)	**Command inputs:** RAS#, CAS#, and WE# (along with S#) define the command being entered.
BA0–BA2	Input (SSTL_18)	**Bank address inputs:** BA0–BA2 define to which device bank an ACTIVE, READ, WRITE, or PRECHARGE command is being applied. BA0–BA2 define which mode register, including MR, EMR, EMR(2), and EMR(3), is loaded during the LOAD MODE command.
A0–A15	Input (SSTL_18)	**Address inputs:** Provide the row address for ACTIVE commands, and the column address and auto precharge bit (A10) for READ/WRITE commands, to select one location out of the memory array in the respective bank. A10 sampled during a PRECHARGE command determines whether the PRECHARGE applies to one device bank (A10 LOW, device bank selected by BA0–BA2) or all device banks (A10 HIGH). The address inputs also provide the op-code during a LOAD MODE command. 4GB modules are addressed by A0–A13; 8GB modules by A0–A14, and A15 is required for register parity function.
PAR_IN	Input (SSTL_18)	Parity bit for the address and control bus.
SCL	Input (SSTL_18)	**Serial clock for presence-detect:** SCL is used to synchronize the presence-detect data transfer to and from the module.
SA0–SA2	Input (SSTL_18)	**Presence-detect address inputs:** These pins are used to configure the presence-detect devices.
RESET#	Input (LVCMOS)	Asynchronously forces all registered outputs LOW when RESET# is LOW. This signal can be used during power up to ensure that CKE is LOW and DQs are High-Z.
DQS0–DQS17, DQS0#–DQS17#	I/O (SSTL_18)	**Data strobe:** Output with read data, input with write data for source synchronous operation. Edge-aligned with read data, center-aligned with write data. DQS# is only used when differential data strobe mode is enabled via the LOAD MODE command.
DQ0–DQ63	I/O (SSTL_18)	**Data input/output:** Bidirectional data bus.
CB0–CB7	I/O (SSTL_18)	Check bits.
SDA	I/O (SSTL18)	**Serial presence-detect data:** SDA is a bidirectional pin used to transfer addresses and data into and out of the presence-detect portion of the module.
ERR_OUT	Output (open drain)	Parity error found on the address and control bus.
VDD	Supply	**Power supply:** 1.8V ±0.1V.
VDDQ	Supply	**DQ power supply:** 1.8V ±0.1V.
VREF	Supply	SSTL_18 reference voltage.
VSS	Supply	Ground.
VDDSPD	Supply	**Serial EEPROM positive power supply:** +1.7V to +3.6V.
NC	–	**No connect:** These pins should be left unconnected.
RFU	–	Reserved for future use.

General Description

The MT36HTJ51272(P)Y, MT36HTS51272(P)Y, and MT36HTS1G72(P)Y DDR2 SDRAM modules are high-speed, CMOS, dynamic random-access 4GB and 8GB memory modules organized in a x72 configuration. These DDR2 SDRAM modules use internally configured 8-bank (1Gb, 2Gb TwinDie, or 4Gb TwinDie) DDR2 SDRAM devices.

DDR2 SDRAM modules use double data rate architecture to achieve high-speed operation. The double data rate architecture is essentially a 4*n*-prefetch architecture with an interface designed to transfer two data words per clock cycle at the I/O pins. A single read or write access for the DDR2 SDRAM module effectively consists of a single 4*n*-bit-wide, one-clock-cycle data transfer at the internal DRAM core and four corresponding *n*-bit-wide, one-half-clock-cycle data transfers at the I/O pins.

A bidirectional data strobe (DQS, DQS#) is transmitted externally, along with data, for use in data capture at the receiver. DQS is a strobe transmitted by the DDR2 SDRAM device during READs and by the memory controller during WRITEs. DQS is edge-aligned with data for READs and center-aligned with data for WRITEs.

DDR2 SDRAM modules operate from a differential clock (CK and CK#); the crossing of CK going HIGH and CK# going LOW will be referred to as the positive edge of CK. Commands are registered at every positive edge of CK. Input data is registered on both edges of DQS, and output data is referenced to both edges of DQS, as well as to both edges of CK.

Register and PLL Operation

DDR2 SDRAM modules operate in registered mode, where the command/address input signals are latched in the registers on the rising clock edge and sent to the DDR2 SDRAM devices on the following rising clock edge (data access is delayed by one clock cycle). A phase-lock loop (PLL) on the module receives and re-drives the differential clock signals (CK, CK#) to the DDR2 SDRAM devices. The register(s) and PLL reduce address, command, control, and clock signal loading by isolating DRAM from the system controller. PLL clock timing is defined by JEDEC specifications and ensured by use of the JEDEC clock reference board. Registered mode will add one clock cycle to CL.

Serial Presence-Detect Operation

DDR2 SDRAM modules incorporate serial presence-detect (SPD). The SPD function is implemented using a 2,048-bit EEPROM. This nonvolatile storage device contains 256 bytes. The first 128 bytes are programmed by Micron to identify the module type and various SDRAM organizations and timing parameters. The remaining 128 bytes of storage are available for use by the customer. System READ/WRITE operations between the master (system logic) and the slave EEPROM device occur via a standard I^2C bus using the DIMM's SCL (clock) and SDA (data) signals, together with SA (2:0), which provide eight unique DIMM/EEPROM addresses. Write protect (WP) is tied to V_{SS} on the module, permanently disabling hardware write protect.

Electrical Specifications

Stresses greater than those listed in Table 8, may cause permanent damage to the module. This is a stress rating only, and functional operation of the module at these or any other conditions above those indicated in each device's data sheet is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Table 8: Absolute Maximum Ratings

T_A	Module ambient operating temperature	Commercial	0	+70	°C
		Industrial	–40	+85	°C
T_C[1]	DDR2 SDRAM component case operating temperature[2]	Commercial	0	+85	°C
		Industrial	–40	+95	°C

Notes:
1. The refresh rate is required to double when $85°C < T_C \leq 95°C$.
2. For further information, refer to technical note TN-00-08: Thermal Applications, available on Micron's Web site.

Input Capacitance

Micron encourages designers to simulate the performance of the module to achieve optimum values. Simulations are significantly more accurate and realistic than a gross estimation of module capacitance when inductance and delay parameters associated with trace lengths are used in simulations. JEDEC modules are currently designed using simulations to close timing budgets.

AC Timing and Operating Conditions

Recommended AC operating conditions are given in the DDR2 component data sheets. Component specifications are available on Micron's Web site. Module speed grades correlate with component speed grades as shown in Table 9.

Table 9: Module and Component Speed Grades

Module Speed Grade	Component Speed Grade

Stop condition setup time	$^tSU:STO$	0.6	–	µs	
WRITE cycle time	^tWRC	–	10	ms	4

Notes:
1. To avoid spurious start and stop conditions, a minimum delay is placed between SCL = 1 and the falling or rising edge of SDA.
2. This parameter is sampled.
3. For a restart condition, or following a WRITE cycle.
4. The SPD EEPROM WRITE cycle time (^tWRC) is the time from a valid stop condition of a write sequence to the end of the EEPROM internal ERASE/PROGRAM cycle. During the WRITE cycle, the EEPROM bus interface circuit is disabled, SDA remains HIGH due to the pull-up resistance, and the EEPROM does not respond to its slave address.
