**Table 6: Pin Descriptions**

Symbol	Type	Description
A0-A12	Input	<b>Address inputs:</b> Provide the row address for ACTIVE commands, and the column address and auto precharge bit (A10) for READ/WRITE commands, to select one location out of the memory array in the respective device bank. A10 sampled during a PRECHARGE command determines whether the PRECHARGE applies to one device bank (A10 LOW, device bank selected by BA0 and BA1) or all device banks (A10 HIGH). The address inputs also provide the op-code during a MODE REGISTER SET command. BA0 and BA1 define which mode register (mode register or extended mode register) is loaded during the LOAD MODE REGISTER command
BA0, BA1	Input	<b>Bank address:</b> BA0 and BA1 define the device bank to which an ACTIVE, READ, WRITE, or PRECHARGE command is being applied.
CK0, CK0#	Input	<b>Clock:</b> CK and CK# are differential clock inputs. All control, command, and address input signals are sampled on the crossing of the positive edge of CK and the negative edge of CK#. Output data (DQ and DQS) is referenced to the crossings of CK and CK#.
CKE0, CEK1	Input	<b>Clock enable:</b> CEK enables (registered HIGH) and disables (registered LOW) the internal clock, input buffers, and output drivers.
DM0-DM8	Input	<b>Input data mask:</b> DM is an input mask signal for write data. Input data is masked when DM is sampled HIGH, along with that input data, during a write access. DM is sampled on both edges of DQS. Although DM pins are input-only, the DM loading is designed to match that of the DQ and DQS pins.
RAS#, CAS#, WE#	Input	<b>Command inputs:</b> RAS#, CAS#, and WE# (along with S#) define the command being entered.
RESET#	Input	<b>Reset:</b> Asynchronously forces all registered outputs LOW when RESET# is LOW. This signal can be used during power-up to ensure that CEK is LOW and DQ are High-Z.
S0#, S1#	Input	<b>Chip selects:</b> S# enables (registered LOW) and disables (registered HIGH) the command decoder.
SA0-SA2	Input	<b>Presence-detect address inputs:</b> These pins are used to configure the SPD EEPROM address range on the I <sup>2</sup> C bus.
SCL	Input	<b>Serial clock for SPD EEPROM:</b> SCL is used to synchronize the presence-detect data transfer to and from the module.
CB0-CB7	I/O	Check bits.
DQ0-DQ63	I/O	<b>Data input/output:</b> Data bus.
DQS0-DQS8	I/O	<b>Data strobe:</b> Output with read data. Edge-aligned with read data. Input with write data. Center-aligned with write data. Used to capture data.
SDA	I/O	<b>Serial data:</b> SDA is a bidirectional pin used to transfer addresses and data into and out of the presence-detect portion of the module.
VDD/VDDQ	Supply	<b>Power supply:</b> +2.5V ±0.2V (-40B: +2.6V ±0.1V).
VDDSPD	Supply	<b>Serial EEPROM power supply:</b> +2.3V to +3.6V.
VREF	Supply	SSTL_2 reference voltage (VDD/2).
VSS	Supply	Ground.
NC	-	<b>No connect:</b> These pins are not connected on the module.

## General Description

The MT18VDDF6472D and MT18VDDF12872D are high-speed, CMOS dynamic random access 512MB and 1GB memory modules organized in a x72 configuration. These modules use DDR SDRAM devices with four internal banks.

DDR SDRAM modules use a double data rate architecture to achieve high-speed operation. The double data rate architecture is essentially a  $2n$ -prefetch architecture with an interface designed to transfer two data words per clock cycle at the I/O pins. A single read or write access for DDR SDRAM modules effectively consists of a single  $2n$ -bit-wide, one-clock-cycle data transfer at the internal DRAM core and two corresponding  $n$ -bit-wide, one-half-clock-cycle data transfers at the I/O pins.

A bidirectional data strobe (DQS) is transmitted externally, along with data, for use in data capture at the receiver. DQS is a strobe transmitted by the DDR SDRAM during READs and by the memory controller during WRITEs. DQS is edge-aligned with data for READs and center-aligned with data for WRITEs.

DDR SDRAM modules operate from differential clock inputs (CK and CK#); the crossing of CK going HIGH and CK# going LOW will be referred to as the positive edge of CK. Control, command, and address signals are registered at every positive edge of CK. Input data is registered on both edges of DQS, and output data is referenced to both edges of DQS, as well as to both edges of CK.

## Register and PLL Operation

These DDR SDRAM modules operate in registered mode, where the control, command, and address input signals are latched in the registers on the rising clock edge and sent to the DDR SDRAM devices on the following rising clock edge (data access is delayed by one clock cycle). A phase-lock loop (PLL) on the module receives and redrives the differential clock signals (CK, CK#) to the DDR SDRAM devices. The register(s) and PLL reduce control, command, address, and clock signals loading by isolating DRAM from the system controller. PLL clock timing is defined by JEDEC specifications and ensured by use of the JEDEC clock reference board. Registered mode will add one clock cycle to CL.

## Serial Presence-Detect Operation

DDR SDRAM modules incorporate serial presence-detect. The SPD data is stored in a 256-byte EEPROM. The first 128 bytes are programmed by Micron to identify the module type and various DDR SDRAM organizations and timing parameters. The remaining 128 bytes of storage are available for use by the customer. System READ/WRITE operations between the master (system logic) and the slave EEPROM device occur via a standard I<sup>2</sup>C bus using the DIMM's SCL (clock) and SDA (data) signals, together with SA[2:0], which provide eight unique DIMM/EEPROM addresses. Write protect (WP) is connected to VSS, permanently disabling hardware write protect.

## Electrical Specifications

Stresses greater than those listed in Table 7 may cause permanent damage to the module. This is a stress rating only, and functional operation of the module at these or any other conditions outside those indicated on the device data sheet is not implied. Exposure to absolute maximum rating conditions for extended periods may adversely affect reliability.

## DRAM Operating Conditions

Recommended AC operating conditions are given in the DDR component data sheets. Component specifications are available on Micron's Web site. Module speed grades correlate with component speed grades, as shown in Table 8.

**Table 8: Module and Component Speed Grades**  
DDR components may exceed the listed module speed grades

## Design Considerations

### Simulations

Micron memory modules are designed to optimize signal integrity through carefully designed terminations, controlled board impedances, routing topologies, trace length matching, and decoupling. However, good signal integrity starts at the system level. Micron encourages designers to simulate the signal characteristics of the system's memory bus to ensure adequate signal integrity of the entire memory system.

### Power

Operating voltages are specified at the DRAM, not at the edge connector of the module. Designers must account for any system voltage drops at anticipated power levels to ensure the required supply voltage is maintained.

- Notes:
1. To avoid spurious start and stop conditions, a minimum delay is placed between SCL = 1 and the falling or rising edge of SDA.
  2. This parameter is sampled.
  3. For a restart condition or following a WRITE cycle.
  4. The SPD EEPROM WRITE cycle time (<sup>t</sup>WRC) is the time from a valid stop condition of a write sequence to the end of the EEPROM internal ERASE/PROGRAM cycle. During the WRITE cycle, the EEPROM bus interface circuit is disabled, SDA remains HIGH due to pull-up resistance, and the EEPROM does not respond to its slave address.
