PRELIMINARY

CYIL1SN3000AA

LUPA 3000: 3 MegaPixel High Speed CMOS Sensor

Features

- 1696 x 1710 active pixels
- 8 µm X 8 µm square pixels
- 1 inch optical format
- Monochrome or color digital output
- 485 fps frame rate
- 64 on-chip 8-bit ADCs
- 32 LVDS serial outputs
- Random programmable ROI readout
- Global pipelined triggered shutter
- Serial Peripheral Interface (SPI)
- Limited supplies: 2.5 V and 3.3 V
- 0 °C to 60 °C Operational temperature range
- 369-pin µPGA package
- Power dissipation: 1.1 W

Applications

- High speed machine vision
- Holographic data storage
- Motion analysis
- Intelligent traffic system
- Medical imaging
- Industrial imaging

Description

The LUPA 3000 is a high speed CMOS image sensor with an image resolution of 1696 by 1710 pixels. The pixels are 8 µm x 8 µm in size and consist of high sensitivity 6T pipelined global shutter capability where integration during readout is possible. The LUPA 3000 delivers 8-bit color or monochrome digital images with a 3 Mpixels resolution at 485 fps that makes this product ideal for high speed vision machine, intelligent traffic system, and holographic data storage. The LUPA 3000 captures complex high speed events for traditional machine vision applications and various high speed imaging applications.

The LUPA 3000 production package is housed in a 369-pin ceramic µPGA package and is available in a monochrome version or Bayer (RGB) patterned color filter array with micro lens. Contact your local Cypress representative for more information.

Specifications

Key Specifications

Table 1. General Specifications

Parameter	Specifications
Active pixels	1696 (H) x 1710 (V)
Pixel size	8 µm x 8 µm
Pixel type	6T pixel architecture
Data rate	412 Mbps (32 serial LVDS outputs)
Shutter type	Global Pipelined Triggered Shutter
Frame rate	485 fps at full frame
Master clock	206 MHz
Windowing (ROI)	Randomly programmable ROI read out. Implemented as scanning of lines or columns from an uploaded position
Read out	Windowed read out
ADC resolution	8-bit, on-chip
Extended dynamic range	Multiple slope (up to 80 dB optical dynamic range)

Table 2. Electro Optical Specifications

Parameter	Specifications
Conversion gain	39.2 µV/e^- at the output
Full well charge	27000e^-
Sensitivity	1270 V.m^2/W.s at 600 nm with microlens
Fill factor	36%
Parasitic light sensitivity	< 1/5000
Dark noise	21e^-
QE x FF	37% at 680 nm with micro lens
FPN	2% of $Vsweep_{RMS}$
PRNU	2.2% of Vsignal
Dark signal	277 mV/s at 25°C
Power dissipation	1.1W at 485 fps

Absolute Maximum Ratings

Table 3. Absolute Maximum Ratings [2]

Symbol	Description	Min	Max	Units
ABS (2.5 V supply group)	ABS rating for 2.5 V supply group	-0.5	3.0	V
ABS (3.3 V supply group)	ABS rating for 3.3 V supply group	-0.5	4.3	V
T_J[2]	Operating temperature range	0	60	°C
T_S[3]	Storage temperature range	20	40	°C
	Storage humidity range	30	60	%RH
ESD[3]	HBM	2000		V
	CDM	500		V
LU	Latchup	200		mA

Notes
1. Absolute maximum ratings are limits beyond which damage may occur.
2. Operating ratings are conditions in which operation of the device is intended to be functional.
3. Cypress recommends that customers become familiar with, and follow the procedures in JEDEC Standard JESD625-A. Refer to Application Note AN52561.

V_{MEM_H}	Memory element high level supply	Operating voltage		-5%	3.3	+5%	V
		Peak current during FOT			90		mA
$V_{PRECHARGE}$	Pre_charge driver supply	Operating voltage		-10%	0.4	+10%	V
		Peak current during FOT	transient duration: 50ns		10		mA
V_{CM}	Common mode voltage	Operating voltage	(Refer toTable 43 on page 31)		0.9		V
		Operating current			10		mA

Notes

4. All parameters are characterized for DC conditions after thermal equilibrium is established.
5. Peak currents are measured without the load capacitor from the LDO (Low Dropout Regulator). The 100 nF capacitor bank is connected to the pin in question.
6. This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields. However, it is recommended that normal precautions be taken to avoid application of any voltages higher than the maximum rated voltages to this high impedance circuit.
7. The V_{MEM_L} power supply should have a sourcing and sinking current capability.

F_{CLK}	Input clock frequency	fps = 485		206	MHz
fps	Frame rate	Maximum clock speed		485	fps

Combining Power Supplies

Every module in the image sensor has its own power supply and ground. The grounds can be combined externally, but not all power supply inputs may be combined. Some power supplies must be isolated to reduce electrical crosstalk and improve shielding, dynamic range, and output swing. Internal to the image sensor, the ground lines of each module are kept separate to improve shielding and electrical crosstalk between them.

The LUPA 3000 contains circuitry to protect the inputs against damage due to high static voltages or electric fields. However, take normal precautions to avoid voltages higher than the maximum rated voltages in this high impedance circuit. Unused inputs must always be tied to an appropriate logic level, for example, V_{DD} or GND. All cap_xxx pins must be connected to ground through a 100 nF capacitor.

The recommended combinations of supplies are:

- Analog group of +2.5 V supply: V_{RES}, V_{RES_DS}, V_{ADC}, V_{pix}, V_{ANA}
- Digital Group of +2.5 V supply: V_{DD}, V_{D_HS}, V_{LVDS}
- The V_{MEM_L} and $V_{PRECHARGE}$supplies should be designed to have sinking and sourcing capability.

Biasing

The sensor requires three biasing resistors. Refer to Table 7 for more more information.

For low frame rates (< 2000 fps), the PRECHARGE_BIAS_1 pins are connected directly with the VPRECHARGE pins. The DC level on the PRECHARGE_BIAS_1 pins acts as a power supply and must be decoupled. For higher frame rates, the duty cycle on VPRECHARGE is too high and the voltage drops. This causes the black level to shift compared to the low frame rate case. In higher frame rates, the voltage on PRECHARGE_BIAS_1 is buffered on PCB and the buffered voltage is taken for VPRECHARGE. A second possibility is to make the biasing resistor larger until the correct DC level is reached.

PRECHARGE_BIAS_2 must be left floating because it is intended for testing purposes.

Table 7. Biasing Resistors Precharge_Bias_1

Signal	Comment	Related Module	DC level
Current_Ref_1	Connect with 20 kΩ (1% prec.) to V_{AA}. Decouple to GND_{AA}	Column amplifiers	769 mV at 86 µA
Current_Ref_2	Connect with 50 kΩ (1% prec.) to GND_{ADC}. No decoupling	ADCs	25 µA to gnd
Precharge_Bias_1	Connect with 90 kΩ (1% prec.) to V_{PIX}. Decouple to Vpix with 100 nF.	Pixel Array	0.45 V at 23 µA
Precharge_Bias_2	Leave floating

Overview

The datasheet describes the interfaces of the LUPA 3000. The CMOS image sensor features synchronous shutter with a maximum frame rate of 485 fps at full resolution.

The sensor contains 64 on-chip 8-bit ADCs operating at 25.75 Msamples/s each, resulting in an aggregate pixel rate of 1.4 Gpix/s. The outputs of the 64 ADCs are multiplexed onto 32 LVDS serial links operating at 412 Mbit/s each resulting in an aggregate date rate of 13.2 Gbits. The 32 data channel LVDS interface allows a very high data rate with a limited number of pins. Each channel runs at 51.5 MSPS pixel rate, which results in 485 fps frame rate at full resolution. Higher frame rates are achieved by windowing which is programmable over the SPI interface.

All required clocks, control, and bias signals are generated on-chip. The incoming high speed clock is divided to generate the different low speed clocks required for the sensor operation. The sensor generates all its bias signals from an internal bandgap reference. An on-chip sequencer generates all the required control signals for the image core, the ADCs, and the on chip digital data processing path. The sequencer settings are stored in registers that can be programmed through the serial command interface. The sequencer supports windowed readout at frame rates up to 10000 fps.

The sensor is available in a monochrome or Bayer (RGB) patterned color filter array and is housed in a 369-pin uPGA package.

Figure 2 shows the spectral response of the mono and color versions of the LUPA 3000.

Figure 3 on page 7 depicts the behavior of the micro lens for mono and color image sensor.

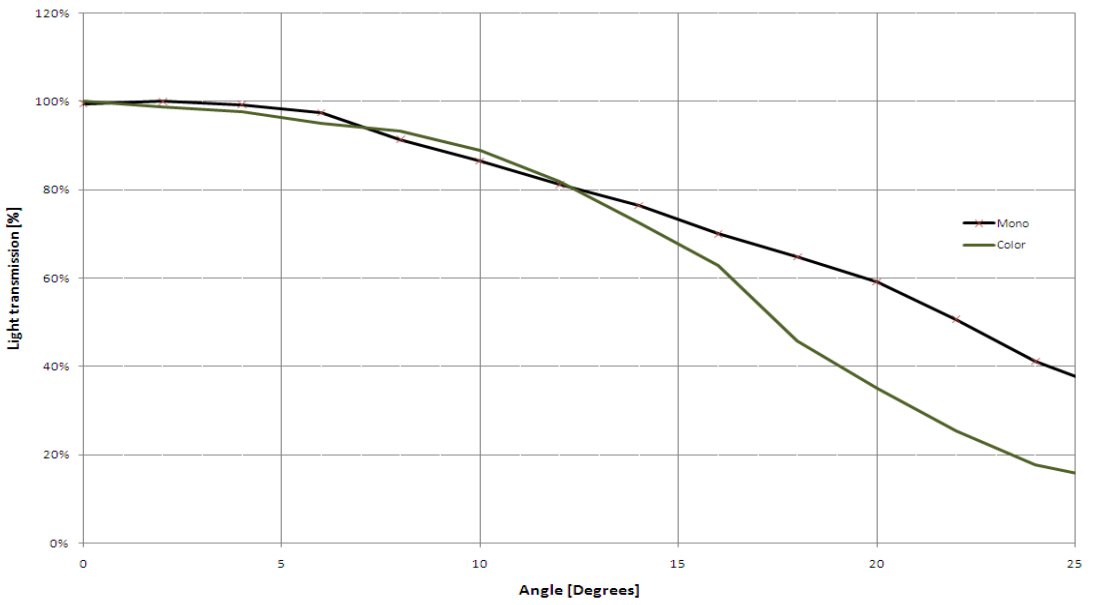
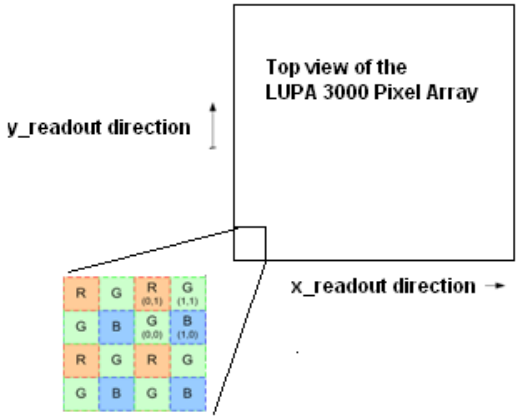
Figure 3. Mono and Color µLens BehavioreColor Filter Array



The color version of LUPA 3000 is available in Bayer (RGB) patterned color filter array. The orientation of RGB and active pixel array [0,0] is shown in Figure 4.

Figure 4. RGB Bayer



Sensor Architecture

Image Sensor Core

The LUPA 3000 floor plan is shown in Figure 5 on page 8. The sensor consists of the pixel array, column amplifiers, analog front end consisting of programmable gain amplifier and ADCs, data block (not shown), sequencer, and LVDS transmitter and receivers. The image sensor of 1696 x 1710 active pixels is read out in progressive scan.

The architecture enables programmable addressing in the x-direction in steps of 32 pixels, and in the y direction in steps of one line. The starting point of the address can be uploaded by the SPI.

The AFE prepares the signal for the digital data block when the data is multiplexed and prepared for the LVDS interface.

Note In Figure 6 on page 8, 32 pixels (1 kernel) are read out, where the MSB bit is the first bit out.

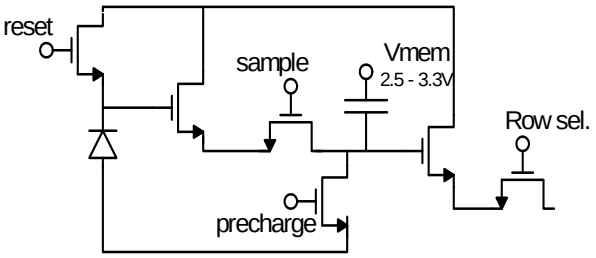
6T Pixel Architecture

The pixel architecture shown in Figure 7 features the global shutter combined with a high sensitivity and good Parasitic Light Sensitivity (PLS). This pixel architecture is designed in an 8 µm x 8 µm pixel pitch and designed with a large fill factor to meet the electro-optical specifications as shown in Table 2 on page 3.

Figure 7. Pixel Schematic



Analog Front End

Programmable Gain Amplifiers

LUPA 3000 includes analog programmable gain amplifiers (before each of the 64 ADCs) to maximize sensor array signal levels to the ADC dynamic range. Six gain settings are available through the SPI register interface to allow 1x, 1.5x, 2x, 2.25x, 3x, or 4x gain.

The entire “analog front end” signal processing and ADC concept for the LUPA 3000 chip are shown in Figure 8.

The analog signal processing “frontend” circuits provide programmable gain level. They also convert the single ended pixel voltage from each column (as referenced to the user programmable Black or Dark reference level) to a “unipolar” differential signal for the PGA (programmable gain amplifier) stages. This is followed by a conversion to a “bipolar” differential signal to maximize the ADC dynamic range and noise immunity.

Figure 8. TAnalog Frontend and ADC Concept

Overview: HDI1 Analog Front-end (Signal Conditioning + Gain) **and ADC Concept**

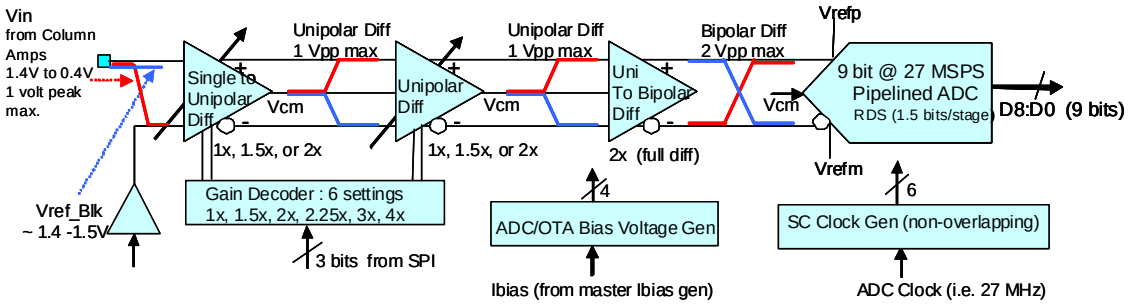


Table 8. Programmable Amplifiers Gain Settings

Register Address d73			Gain Level	Comments
Bit 2	Bit 1	Bit 0		
0	0	0	1x	POR default value
0	0	1	1.5x	
0	1	0	2.0x	
0	1	1	2.25x	
1	0	0	3.0x	
1	0	1	4.0x	
1	1	x	3.0x	Do not use (Redundant gain codes)

The gain is set through bits 2:0 in register 73 (decimal).

The gain register controls the gain setting globally for all 64 PGA and ADC channels.

A latency (delay) is incurred for the analog signal processing, PGA, and ADC stages. The total latency is 44 high speed input clock delays. The output synchronization signals from the LVDS “sync” channel factor in this latency.

[+] Feedback

Programmable Dark Level

A SPI controlled DAC provides the programmable gain amplifiers with a dark level. This analog voltage corresponds with the all zero output of the ADC. This dark level is tuned to optimally use the ADC range.

The dark level coming from the pixels follow a Gaussian distribution. This distribution is visible in a dark image as the FPN. The spread on the distribution is influenced by the dark current and temperature. Typically the spread is 100 mV peak to peak.

The average dark level of this distribution depends on several parameters:

- The processing corner
- Tolerances on the pixel power supplies (Vpix, Vreset, Vmem_l, and Vmem_h)
- Pixel timing

The combination of these parameters adds an offset to the dark level. The offset is in the order of magnitude of 200 mV.

To allow off-chip FPN calibration, the full spread on the dark level is mapped inside the range of the ADC. To optimally use the input range of the ADC, the spread on the dark level is mapped as close as possible to the high level of the ADC's input range.

The default startup value of the dark level coming from the DAC is 1.5 V. This ensures that the spread on the dark level is completely mapped in the range of the ADC. The startup DAC dark level is not optimal. By taking a dark image after startup, the offset on the dark image histogram is measured. The offset from the optimal case is subtracted from the dark level coming from the DAC. This places the dark level distribution optimally inside the range of the ADC. This procedure is followed after every change in operation condition such as temperature, FOT timing, and ROT.

Analog to Digital Converters

LUPA 3000 includes 64 pipelined 9-bit analog to digital converters (ADCs) operating at approximately 25.75 mega samples per second (MSPS). Two ADCs are combined to provide digitized data to one of the 32 LVDS serialization channels. One of the ADC pair converts data from an "odd kernel" of the LUPA 3000 pixel array, the other from an 'even kernel". LUPA 3000 only processes the eight MSBs of the converter to realize an improved noise performance 8-bit converter.

The ADCs are designed using fully differential circuits to improve performance and noise immunity. In addition, an RSD (redundant signed digit) 1.5 bit per stage architecture with digital error correction is used to improve DNL and ensure that no codes are missing. Interstage ADC gain errors are addressed using commutation techniques for capacitor matching. Auto-zeroing and other calibration methods are implemented to remove offsets.

The ADCs digitize up to a maximum of one volt signals from the pixel array core. This provides a maximum internal dynamic range to the ADC of two Vp-p (bipolar differential). The dynamic range is set by the difference of the Vrefp-Vrefm reference levels. The reference levels are available at LUPA 3000 package pins for external decoupling.

References and Programmable Trimming

Bits 6:4 of SPI register 64 (decimal) allow adjustment of the Vrefp-Vrefm differential ADC reference level. Eight settings are provided to enable trimming of the dynamic range. Reduced dynamic range is used to optimize signals in low light intensity, where reduced pixel levels require further gain. Table 9 provides the permitted trim settings.

Table 9. Programmable ADC Reference Level

Register Address 64 (dec) Bit 6	Bit 5	Bit 4	Vrefp-Vrefm Gain Level (typ)	Comments
0	0	0	0.5x	Maximum effective gain +6.0 dB (2x)
0	0	1	0.67x	
0	1	0	0.71x	
0	1	1	0.77x	
1	0	0	0.83x	
1	0	1	0.91x	Available setting to ensure 0 code
1	1	0	0.95x	Available setting to ensure 0 code
1	1	1	1.0 x	POR (startup) default level

The black voltage level from the pixel array is more positive than the user set Vdark or "black" reference level. This results in a nonzero differential voltage in the PGAs and other AFE stages. This condition prevents obtaining a desired 0 code out of the ADCs. The 0.95x and 0.91x trim settings are specifically supplied to allow minor adjustment to the ADC differential reference (Vrefp-Vrefm) to ensure a 0 level code in these conditions.

The additional trim settings are provided as dynamic range adjustments in low light intensities to act as effective global gain settings. The absolute level of gain (from the typical values) are not guaranteed. However, the gain increases are monotonic. Approximately 2x (+6.0 dB) is the maximum gain obtainable using this method. As a result, the combined gain of both PGAs and the ADC reference trimming available is 8x maximum.

Some reference voltages are overdriven after the on-chip control logic is powered down (refer section On-Chip BandGap Reference and Current Biasing on page 16). Overdriving, a feature intended for testing and debugging, is not recommended for normal operation. The reference voltages that are overdriven are:

- Vrefp - Vrefm (can be overdriven as a pair)
- Vcm
- Vdark
- Internal bandgap voltage

Table 10 summarizes the ADC and AFE (signal processing) parameters.

Downloaded from Elcodis.com electronic components distributor

[+] Feedback

Table 10. AFE and ADC Parameters

Parameter	Parameter Value (typical)	Comment
Input range (Single to Diff Converter; S2D)	1.5 V–0.3 V (SE to Unipolar Differential)	S2D performs inversion. Referenced from Vblack
Vblack	1.2 V–1.5 V (typical)	Dark or black level reference from SPI programmable DAC. 0.01 µF to gnd.
Analog PGA gain and settings	1x–4x (6 gain settings)	3-bit SPI programmable. 1x, 1.5x, 2x, 2.25x, 3x, 4x
Input range (ADC)	0.75 V–1.75 V	1V maximum Vrefp-Vrefm (2 Vp-p maximum)
ADC type	Pipelined (four ADC clock latency)	With digital error correction (no missing codes)
ADC resolution	8 bits	
Sampling rate per ADC	26.5 MSPS	Maximum 30 MSPS
ENOB	7.5 bits	Effective number of bits
DNL	±0.5 LSB	No missing codes
INL	±1.0 LSB	
Power supply	2.5 V ±0.25V	
Total AFE + ADC latency	44 Master clocks	5.5 ADC clocks = 1/8 of master clk
Total AFE + ADC power (32 channels = 64 AFE + ADC)	400 mW (at 2.5 V)	160 mA

Each pair of odd and even kernel AFE + ADC channels are individually powered down with its associated LVDS serialization channel. This is controlled through bits in SPI registers 66–70 (decimal). Logic 1 is the power down state. The POR defaults are logic 0 for all channels powered on.

Protocol Layer

Digital data from the ADCs is reorganized in the protocol layer before it is transferred to the LVDS drivers. The following operations are performed in the protocol layer:

- Multiplexing of two ADCs to one output data channel
- Addition of the CRC checksum to the data stream. This operation is done row by row. A new CRC checksum is calculated for every new row that is readout.
- Switching readout mode. The LUPA 3000 sensor is programmed to operate in two other readout modes: training and test image modes. These modes synchronize the readout circuitry of the end user with the sensor.
- Assembling the data stream of the synchronization channel.

CRC

LUPA 3000 implements a Cyclic Redundancy Check (CRC) for each row (line) of processed data to detect errors during the high speed transmission. CRC provides error detection capability at low cost and overhead.

The CRC polynomial implemented for LUPA 3000 is: x^8+x^6+x^3+x^2+1.

The CRC result is transmitted with the original data. When the data is received (or recovered), the CRC algorithm is reapplied and the latest result compared to the original result. If a transmission error occurs, a different CRC result may be obtained. The system then chooses to operate on the detected error or has the frame resent.

The CRC shift register is initialized with logic 1s at reset to improve bit error detection efficiency.

Referring to Figure 9, the CRC value is calculated for each row and inserted into the serial data stream. Bit 0 of SPI register 71 (decimal) is an enable bit to insert the CRC checksum. CRC is enabled when a logic 1 is written to this bit. This is the default (POR) value. Bit 1 of this register allows calculation and insertion of a CRC checksum to the “synchronization” channel. No checksum is attached by default.

Figure 9. Equivalent Polynomial Representation in Serial Format

[+] Feedback

Data Block

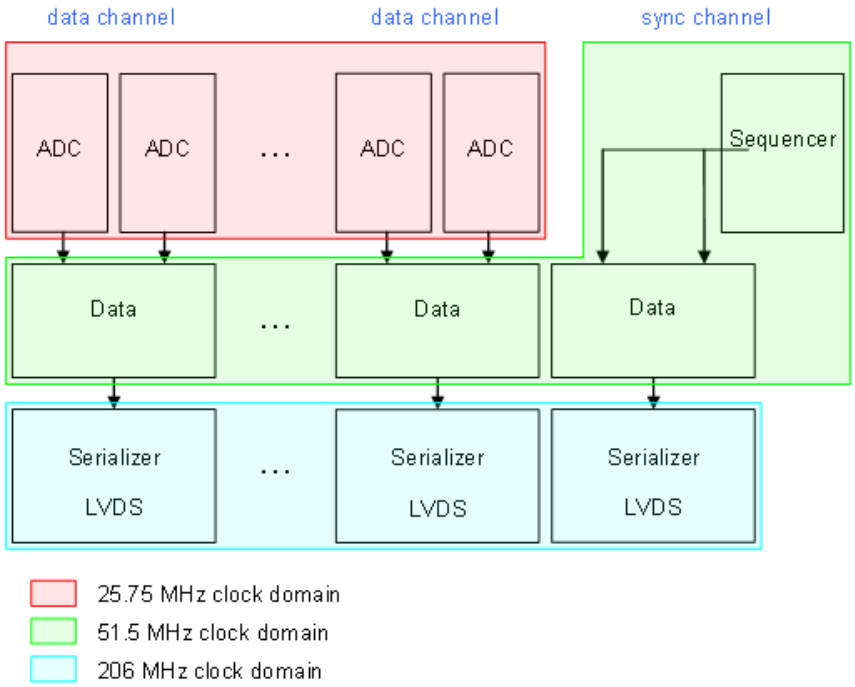
The data block is positioned in between the analog front end (output stage+ADCs) and the LVDS interface. It muxes the outputs of two ADCs to one LVDS block and performs some minor data handling:

- CRC calculation and insertion
- Training and test pattern generation

It also contains a huge part of the functionality for black level calibration.

A number of data blocks are placed in parallel to serve all data output channels. One additional channel generates the synchronization protocol. A high level overview is illustrated in the following figure.

Figure 10. Data Block



LVDS

LUPA 3000 uses LVDS (low voltage differential signaling) I/O. LVDS offers low power and low noise coupling. It also offers low EMI emissions that are essential for the high data readout rates that are required by the LUPA 3000 image sensor. LVDS voltage swings range from 250 mV to 450 mV with a typical of 350 mV. Because of the low voltage swings, rise and fall times are reduced, enabling higher operating speeds than CMOS, TTL, or other drivers operating at the same slew rate. It uses a common mode voltage ~1.2 V to 1.25 V above ground, and as a result is more independent of the power supply level and less susceptible to noise. Differential transmission also reduces EMI levels. The 2-pin differential output drives a cable with approximately 100 Ω characteristic impedance, which is “far-end” terminated with 100 Ω.

LVDS Data Channels

LUPA 3000 has 32 LVDS data output channels operating at a DDR (Double Date Rate) of 412 Mb per second (typical) using a 206 MHz input clock. The LVDS data channels have a high speed parallel to the serial converter logic function (serializer) that serializes the 52 MS per second 8-bit parallel data from a time multiplexed odd and even kernel ADC pair. The high speed serial bit stream drives a LVDS output driver.

The LVDS driver must deliver positive or negative current through a 2-pin differential output to represent a logical 1 and logical 0 state respectively. The driver is designed in compliance with the ANSI/TIA/EIA-644-A-2001 standard. The circuit consists of a programmable current sink that defines the drive current, a dynamically controlled current source, a 4-transistor bridge that steers these currents to the differential outputs, and a common mode feedback circuit to balance the sink and source currents.

The LVDS standard defines the drive current between 2.5 to 4.5 mA. The termination resistance is specified from 90 Ω to 132 Ω. To allow flexibility in power consumption, the output drive current is programmed through the SPI register interface. Settings are available for operation outside the specified ANSI standard to allow custom settings for power and speed enhancements. These settings may require the use of nonstandard termination resistance. Current drive programming is accomplished using bits 3:0 of SPI register 72 (decimal – LVDS trim). Figure 11 on page 13 defines the programmable LVDS output current settings.

LVDS Sync Channel

LUPA 3000 includes a LVDS output channel to encode sensor synchronization control words such as Start of Frame (SOF), Start of Line (SOL), End of Line (EOL), idle words (IdleA and IdleB), and the sensor line address.

This channel includes a “Serializer” logic section but receives its input directly from the image core sequencer. An additional synchronization control logic block ensures proper data alignment of the synchronization codes to account for the latency incurred in the other 32 data channels (due to AFE and ADC signal processing). The LVDS output driver is similar to that used in other data channel outputs.

LVDS Clk (Clock) Output

The LUPA 3000 provides a LVDS clock output channel. This channel provides an output clock that is in phase and aligned with the data bit stream of the 32 data channels. It is required for clock and data recovery by the system processing circuits.

A “serializer” logic section is connected to accept the differential CMOS “serializer” clock, after processing through the clock distribution buffer network that provides clocks to all LUPA 3000 data channels. The “group delay” of the output clock and data channels is ~2.5 ns relative to the incoming master clock. The LVDS output driver is similar to that used in other data channel outputs.

LVDS CLK (Clock) Input

LUPA 3000 includes a differential LVDS receiver for the master input clock. The input clock rate is typically 206 MHz and also complies with the ANSI LVDS receiver standards. The input clock drives the internal clock generator circuit that produces the required internal clocks for image core and sequencer, AFE and ADCs, CRC insertion logic, and serializers. LUPA 3000 requires the following internal clock domains (all internal clock domains are 2.5 V CMOS levels):

- Serializer clock = 1x differential version of the input clock (206 MHz typical)
- CRC clock = 1/4x the input clock (51.5 MHz typical)
- LOAD pulse = 1/4 (the input clock)at 12.5% duty cycle version of the input clock: for load and handshake between CRC parallel data to serializer.
- ADC and AFE clock = 1/8x the input clock (25.75 MHz typical)
- Sensor Clock = 1/4x the input clock (51.5 MHz typical) with programmable delay
- ADC clock =1/8x the input clock (25.75 MHz typical) with programmable delay

All clock domains are designed with identical clock buffer networks to ensure equal “group delays” and maintain < 100 ps maximum channel to channel clock variation.

Programmable delay adjustment is provided for the clock domains of image sensor core and sequencer. This adjustment optimizes the data acquisition handshaking between the image sensor core and the digitization and serialization channels. SPI register 65 (decimal) controls delay (or advance) adjustments for these two clocks. For each of these two imager clocks, 15 adjustments settings are provided. Each setting allows adjustment for 1/(2x master clock) adjustment. For example, if the master input clock runs at 206 MHz, 1/412Mhz = 2.41 ns adjustment resolution is possible. Refer the section Sensor Clock Edge Adjust Register (b1000001 / d65) on page 27 for programming details.

Cypress provides default settings for the programmable delay. These settings allow correct operation; there is no need to change these settings (unless for testing).

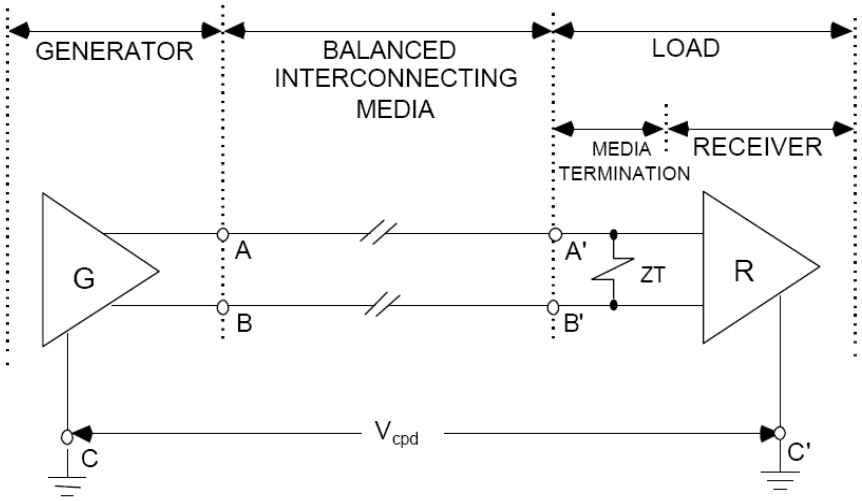
LVDS Specifications

The LUPA 3000 features a 33 channel LVDS data interface, which enables high data rates at a limited pin count with low power and noise. The LUPA 3000 guarantees 412 Mbps transmission over all channels accumulating to an aggregate guaranteed data rate of 13.6 Gbps. The transmission medium can be PCB traces, backplanes, or cables with a characteristic impedance of approximately 100 Ω.

Figure 12. Overview of LVDS Setup



The LUPA 3000 accepts an LVDS input clock to generate and synchronize the serial data stream. The clock used to synchronize all the data channels is transmitted over the thirty fourth channel. This clock signal recovers the data on the receive end without the need for clock recovery. The receiver must feature per channel skew correction to account for on-chip mismatches and intrinsic delays, and also for interconnect medium mismatches.

The LVDS outputs comply to the ANSI/TIA/EIA-644 and IEEE 1596.3 standards. The main specifications are described in the standard. Following the measurement conditions of the standard, the LUPA 3000 LVDS drivers feature the specifications listed in Table 11 on page 15.

Table 11. LVDS Driver Specifications

Parameter	Description	Specification (guaranteed by design)			Units
		Min	Typ	Max	
$\|V_T\|$ [7]	Differential logic voltage	247	350	454	mV
$\|V_T(1)\|-\|V_T(0)\|$	Delta differential voltage			50	mV
V_{OS}	Common mode offset	1.125	1.25	1.375	V
$d\|V_{OS}\|$	Difference in common mode voltage for logic 1 and 0			50	mV
I_{SA}/I_{SB}	Output currents in short to ground condition			24	mA
I_{SAB}	Output current in differential short condition			12	mA
t_r t_f	Differential rise and fall time	400		250	ps
$\|V_{ring}\|$	Differential over and undershoot			$0.2*V_T$	V
$d\|V_{OS}\|$	Dynamic common mode offset			150	mV_{PP}
ZT	Termination resistance	90	100	132	Ω
ZC(f)	Characteristic impedance of the interconnect	90		132	Ω
I_{OFF}	Offstate current			10	µA
t_{SKD1}	Differential skew			0.25	ns
t_{SKD2}	Differential channel to channel skew			0.5	ns
t_{SKCD1}	Differential clock out to data skew			1	ns
t_{SKCD2}	Differential clock in to data skew			3	ns
t_{jit_rms} [8]	Random jitter			50	ps
t_{jit_det} [9]	Deterministic jitter			500	ps
f_{MAX}	Maximum operating frequency			206	MHz
f_{MIN} [10]	Minimum operating frequency	1			MHz

Output trace characteristics affect the performance of the LUPA 3000 interface. Use controlled impedance traces to match trace impedance to the transmission medium. The best practice regarding noise coupling and reflections is to run the differential pairs close together. Limit skew due to receiver end limitations and for reasons of EMI reduction. Matching the differential traces is very important.

Common mode and interconnect media specifications are identical to LVDS receiver specifications.

Table 12. LVDS Receiver Specifications

Parameter	Description	Specification (guaranteed by design			Units
		Min	Typ	Max	
I_{IA}, I_{IB}	Input current			20	µA
I_{IA}-I_{IB}	Input current unbalance			6	µA
Z_T	Required external termination	90	100	132	Ω
$\|V_{ID}\|$	Differential input	100		600	mV
V_{IH}, V_{IL}	minimum and maximum input voltages	0		2.4	V
T_{JIT_TOT}	Total jitter at LUPA 3000 clock input			500	ps

Notes

8. The driver output swing is tuned through the LVDS driver bias current settings in the SPI register. This feature is also used to reduce the power consumption. Alternatively, decrease the termination resistor to boost the speed and keep the swing identical by increasing the bias current.
9. Jitter with reference to LUPA 3000 input clock
10. This is from LVDS point of view, from sensor point of view fMIN is 4 MHz (about 10 fps). At lower speeds dark current and storage node leakage starts influencing the image quality.

On-Chip BandGap Reference and Current Biasing

For current biasing and voltage reference requirements for the AFEs, ADCs, and LVDS I/O, LUPA 3000 includes a bandgap voltage reference that is typically 1.25V. This reference is used to generate the differential Vrefp–Vrefm ADC reference and a analog voltage reference for the LVDS driver I/O.

The bandgap reference voltage also forms a stable current reference for the LVDS drivers and bias currents for all of the analog amplifiers. A “Current-Ref_2” pin is included on the package to allow connection of an ~ 50K resistor (±1%) to gnd to realize a desired 25A current sourced from the LUPA 3000 device. A buffered version of the internal bandgap reference is monitored at this pin.

An optional mode is available to enable an external bandgap regulator. Control bits in SPI register 74 (decimal) allow this feature. Bit 2 is a power down control bit for the internal bandgap. Setting this bit high along with bit 1 (int_res), and bit 0 (bg_disable), allow driving the “Current_Ref_2” pin with an external reference. An internal current reference resistor of 50K to ground is applied (This mode has reduced current accuracy (~ ± 10% from the external resistor mode (± 1%).

Five trimming levels for the internal bandgap voltage are available through bits 2:0 of SPI register 64 (decimal). This allows minor adjustment in process variations for voltage level and temperature tracking. A POR value is preset so that user adjustment is not required (see the register definition for exact settings). Each setting adjusts an internal resistor value used to adjust the PTAT (proportional to absolute temperature) “K” factor ratio. Each of the five settings affect the “K” trimming factor by ~ 1.2%. Minor adjustments are made to tune the reference voltage level and temperature tracking rate to compensate for IC processing variations.

The reference generation circuits also form the internal analog common mode voltage for the differential analog circuits. The Vcm level is available at a package pin for external decoupling and should be driven by a 0.9V supply (refer to Table 43 on page 31). The Vdark or “black” level reference supplied from an on-chip SPI programmable DAC is also buffered and distributed on-chip as input to each of the 64 AFE and ADC channels. This signal is also available at a package pin for external decoupling. Separate power down control bits are available for the differential ADC reference (Vrefp–Vrefm), Vcm, and Vdark. When any of these are powered down, external references are driven on the external package pins. Table 13 overviews primary parameters for the references and biases.

Table 13. Reference and Bias Parameters

Parameter	Parameter Value (Typical)	Comment
Vrefp	1.7 V to 1.75 V	At Vdd=2.5 V. Requires 0.01 µF to gnd.
Vrefm	0.8 V to 0.75 V	At Vdd=2.5 V. Requires 0.01 µF to gnd.
Vrefp–Vrefm	0.95 V to 1.0 V (difference)	ADC range. 3 bit SPI trim settings 1x, 0.95x, 0.91x, 0.83x, 0.77x, 0.71x, 0.67x, 0.5x.
Vcm	0.9 V	External power supply voltage. Requires 10 nF to gnd. Refer to Table 43 on page 31.
Current_Ref_2	1.25 V ± 0.1 V at 25 µA to gnd	Must pull down to gnd with ~ 50 kΩ.
BandGap Reference (internal)	1.25 V ± 0.05 V at 2.5 V, T = 40 °C	Typical < 50 PPM. Level and tracking are 3 bit SPI trimmable. Five settings at ~ 1.2% adjust per step.

Detailed Description of Internal Registers

All registers are reset to their default value when RESET_N is low. When the chip is not in reset, all registers are written and read through the SPI interface. The registers are written when the on-chip sequencer is in reset (RESET_N_SEQ bit is low). Resetting the sequencer has no influence on the SPI registers.

Registers are written during normal operation. However, this influences image characteristics such as black level or interrupts readout. To avoid this, change registers at the appropriate moment during operation.

Registers that control the readout and reference voltages are changed during the FOT (when FOT pin is high). Registers that are used for pixel timing are changed outside the FOT (when FOT pin is low). Change SPI registers when the RESET_N_SEQ bit is low.

SPI Registers

Sequencer Register (b0000000 / d0)

The sequencer register controls the power down of the analog core and the different modes of the sequencer. Bits <7:6> are ignored. The sequencer register contains several sub registers.

- **Powerdown, bit <0>**. Setting this bit high brings the image core in power down mode. It shuts down all analog amplifiers.
- **Reset_n_seq, bit<1>.** Bringing this bit low resets the on-chip sequencer. This allows interruption of light integration and readout. Bringing the bit high triggers a new readout and integration cycle in the sequencer.
- **Red_ROT, bit<2>.** Setting this bit activates the reduced ROT mode. This mode allows increasing the frame rate at a possibly reduced dynamic range. The reduction in dynamic range depends on the length of the ROT . See “ROT_timer (b0000001 / d1)” on page 20. The default timing is in reduced ROT mode, so there is no reduction in dynamic range.

Downloaded from Elcodis.com electronic components distributor

[+] Feedback

- **Ds_en, bit<3>.** Bit to enable dual slope operation. Enabling this mode allows to enlarge optical dynamic range.
- **Sel_pre_width, bit<5:4>.** Setting these 2 bits allows changing the width of the sel_pre pulse that is used to precharge all column lines at the start of every ROT. Changing these bits does not change the total ROT length.

Table 15. Sequencer Register

Value	Effect
Powerdown, bit <0>	
0	Normal operation
1	Image core in power down
On startup	0
Reset_n_seq, bit<1>	
0	Sequencer kept in reset
1	Normal operation
On startup	1
Red_ROT, bit<2>	
0	Long ROT mode
1	Reduced ROT mode
On startup	1
Ds_en, bit<3>	
0	Disable dual slope operation
1	Enable dual slope operation
On startup	0
Sel_pre_width, bit<5:4>	
00	Sel_pre is 1 sensor clock period long (4 master clocks)
01	Sel_pre is 2 sensor clock periods long (8 master clocks)
10	Sel_pre is 3 sensor clock periods long (12 master clocks)
11	Same effect as ‘10’ setting
On startup	00

ROT_timer (b0000001 / d1)

The ROT_timer register controls the length of the ROT. The ROT length, in number of sensor clock periods, is expressed by the formula: ROT length = ROT_timer + 2

The relation between the Row Overhead Time and the ROT pin is described in the section ROT Pin on page 42 Bits <7:5> are ignored.

Table 16. ROT Timer Register

Value bit<4:0>	Effect
00000	ROT length is 35 sensor clocks, 140 master clocks.
xxxxx	ROT length is <N+2> sensor clocks (<N+2>*4 master clocks) where N is the register value
On startup	00111 (9 sensor clocks)

[+] Feedback

Precharge_timer (b0000010 / d2)

The precharge_timer register controls the length of the pixel precharge pulse as described in the section Frame Overhead Time on page 41 The pixel precharge length is expressed in the number of sensor clock periods by the following formula:

Pixel precharge length = precharge_timer x 4

Table 17. Precharge Timer Register

Value	Effect
00000000	Pixel precharge length is 1 sensor clock
xxxxxxxx	Pixel precharge length is <N*4> sensor clocks (<N*4>*4 master clocks), where N is the register value
On startup	00010011

Sample_timer (b0000011 / d3)

The sample_timer register controls the length of the pixel sample pulse as described in the section Frame Overhead Time on page 41. The length of the pixel sample is expressed in the number of sensor clock periods by the following formula:

Pixel sample length = sample_timer x 4

Sample_timer must be equal to or larger than precharge_timer.

Table 18. Sample Timer Register

Value	Effect
00000000	Pixel sample length is two sensor clock
xxxxxxxx	Pixel sample length is <N*4> sensor clocks (<N*4>*4 master clocks), where N is the register value
On startup	00011111

Vmem_timer (b0000100 / d4)

The vmem_timer register controls the length of the pixel vmem pulse as described in the section Frame Overhead Time on page 41. The length of the pixel vmem is expressed in the number of sensor clock periods by the following formula:

Pixel vmem length = vmem_timer x 4

Vmem_timer must be equal to or larger than sample_timer.

Table 19. Vmem Timer Register

Value	Effect
00000000	Pixel vmem length is four sensor clock.
xxxxxxxx	Pixel vmem length is <N*4> sensor clocks (<N*4>*4 master clocks), where N is the register value
On startup	00100010

Fot_timer (b0000101 / d5)

The fot_timer register controls the length of the Frame Overhead Time as described in the section Frame Overhead Time on page 41. The length of the FOT is expressed in the number of sensor clock periods by the following formula:

FOT length = fot_timer x 4 + 2

The relation between the Frame Overhead Time and the FOT pin is described in the section FOT Pin on page 42. Fot_timer must be larger than vmem_timer.

Table 20. Fot_timer Register

Value	Effect
00000000	Invalid setting
xxxxxxxx	FOT length is <N*4+2> sensor clocks (<N*4+2>*4 master clocks), where N is the register value
On startup	00101000

Nb_of_kernels (b0000110 / d6)

This register controls the window size in X. The value of the register determines the number of pixel kernels that is readout every line. The maximum number of kernels to readout is 53. The minimum number of kernels to readout is four.

Bits <7:6> are ignored.

Table 21. Nb_of_Kernels Register

Value bit<5:0>	Effect
000100	Window size in X is 4 kernels
000101	Window size in X is 5 kernels
…	
110101	Window size in X is 53 kernels
On startup	110101

Y_start (b0000111 / d7 and b0001000 / d8)

The Y_start register contains the row address of the Y start pointer. Because a row address is 11 bit wide, the Y_start address is split over 2 registers: Y_start<10:8> and Y_start<7:0>. Y_start<10:8> contains the 3 MSBs of the 11 bit address, and Y_start<7:0> contains the 8 LSBs of the address. Y_start<10:0> must not be larger than 1709.

Table 22. Y_Start Register

Value bit<2:0>	Effect
Y_start<7:0> (b0000111 / d7)	
On startup	00000000
Y_start<10:8> (b0001000 / d8): Bits<7:3> are ignored	
On startup	00000000

Y_end (b0001001 / d9 and b0001010 / d10)

The Y_end register contains the row address of the last row to readout. Because a row address is 11 bit wide, the Y_end address is split over 2 registers: Y_end<10:8> and Y_end<7:0>. Y_end<10:8> contains the 3 MSBs of the 11 bit address, and Y_end<7:0> contains the 8 LSBs of the address. Y_end<10:0> must be larger than Y_start<10:0> and not larger than 1709.

Table 23. Y_End Register

Value bit<2:0>	Effect
Y_end<7:0> (b0001001 / d9)	
On startup	10101101
Y_end<10:8> (b0001010 / d10): Bits<7:3> are ignored	
On startup	00000110

X_start (b0001011 / d11)

The X_start register contains the start position for the X readout. Readout in X starts only at odd kernel positions. As a result, possible start positions are 64 columns (2 kernels) separated from each other.

Bits <7:5> are ignored.

Table 24. X_Start Register

Value bit<4:0>	Effect
00000	X readout starts with the first kernel (column 0)
00001	X readout starts with the third kernel (column 64)
11010	X readout starts with the fifty third kernel (column 1664)
On startup	00000

Training (b0001100 / d12)

This register allows switching between different readout modes. Bits <7:2> are ignored.

- **Training_en, bit<0>.** In bypass mode, this bit is evaluated and determines if the training pattern or test image is transmitted.
- **Bypass_mode, bit<1>**. This bit allows the sensor to switch between normal readout of an image and readout for testing or training purposes.
- **Analog_out_en, bit<2>.** This bit activates the analog output of the sensor. The analog value of column<1696> is brought to the output.

Table 25. Training Register

Value	Effect
Training_en, bit<0>	
1	In bypass mode, the training pattern is transmitted
0	In bypass mode, the test image is transmitted
On startup	0
Bypass_mode, bit<1>	
0	Normal readout of captured images
1	Bypass mode readout. The content of register TRAINING_EN is evaluated.
On startup	0
Analog_out_en, bit<2>	
0	Analog output disabled
1	Analog output enabled
On startup	0

Black_ref (b0001101 / d13)

This register controls the DAC that sets the dark level for the ADC. The analog output of the DAC corresponds with the all 0 code of the ADC. The DAC has an 8-bit resolution and outputs between VAA2V5 and 0V. This means that the step size corresponds with about 9.8 mV. The DAC itself outputs between VAA2V5 and 0V, but the buffering circuit that follows after the DAC clips the voltage close to ground and supply.

Table 26. Black_Ref Register

Value	Effect
00000000	Output of DAC is VAA2V5
00000001	Output of DAC is VAA2V5-9.8mV
…	
11111111	Output of DAC is 0V
On startup	01100110

Bias_col_load (b0001110 / d14)

This register controls the biasing current of the column load. A higher biasing current has the following effects:

- Faster settling on the pixel columns
- Increased power consumption from Vpix.
- Lower dark level

Bias current changes 1.56 µA per LSB. Bits <7:6> are ignored.

ADC and LVDS Channel Powerdown Registers (b1000010- 1000110 / d66-70)

Each of the 32 data channels, sync, and clock out LVDS channels are individually powered down by setting the appropriate bits of these registers. Powering down a channel stops the clock for the odd and even ADCs and LVDS serializer, and turns off the LVDS output driver. Note that the enable pwd_ena in register d71 is set for these bits to take affect. Bits 31:0 are used for data channels 31:0 respectively. Setting bit 33 powers down the output clock channel; bit 32 powers down the sync channel. Setting a particular bit high brings the selected channel to its power down mode.

Misc1 SuperBlk Control Register (b1000111 / d71)

The misc1 superblk control register contains several control and test enable bits. The superblk refers to the AFE, ADC, CRC, Serialization, and LVDS channels and supporting controls.

- **crc_en, bit <0>**. This bit enables inserting crc words into the data channels at the end of a row of image data. Protocol Layer on page 11contains more details on this protocol.
- **crc_sync_en, bit<1>**: This bit enables inserting crc words into the sync channel. This is generally not desired.
- **pwd_ena, bit<2>**. This bit provides the ability to power down individual channels through the pwd_chan registers.
- **pwd_glob, bit<3>**. This bit, when set, globally powers down all 32 data channels, the sync channel, and the clock out channel. This overrides the per channel power down controls.
- **test_en, bit<4>**. This bit is provided to test the serial LVDS output drivers. When set, the LVDS output clock is routed to all output data channels. This is intended for debug and testing only.
- **atst_en, bit<5>.** This bit enables driving an external analog input voltage to the 64 ADCs for testing. When set, the external pin Analog_in and Vdark reference are sent to all ADCs.
- **sblk_spare1, bit<6>.** This bit is a spare control bit. It is set to 0 at POR.
- **sblk_spare2, bit<7>.**: This bit is a spare control bit. It is set to 1 at POR.

LVDS Output Current Adjust Register (b1001000 / d72)

The LVDS output drive current is adjusted with this control register. The startup value is b0110 that represents 3.76 mA, reflecting the typical LVDS operating point. There are 16 programmable values available. For more information refer the section LVDS Data Channels on page 12.

Programmable Gain Register (b1001001 / d73)

The amount of analog gain (in the AFE) is adjusted from 1x–4x in eight steps. This is used with the vref_trim register to match the ADC dynamic range to the pixel voltage range. The startup value for this register is b000, which corresponds to a unity gain (1x). Refer to the section Programmable Gain Amplifiers on page 9 for information on the control bit to gain setting table relationship.

Serial Peripheral Interface (SPI)

The SPI registers have an address space of 7 bits, a<6>–a<0>, and 8 data bits, d<7>–d<0>. A single instruction bit chooses between a read or write instruction.

The SPI is used only after the clock has started and the chip is not in reset. Otherwise the SPI register is kept in reset. SPI registers are reset to their default value by bringing RESET_N low. The SPI bit RESET_N_SEQ has no effect on the SPI bits.

Setup and hold requirements of interface signals relative to SPI_CLK are for both requirements 2.5 ns. Output delay is 1.5 ns after falling edge of SPI_CLK. Rise time (10%–90%) is 9 ns assuming a 18 pF load. To upload SPI, follow this sequence:

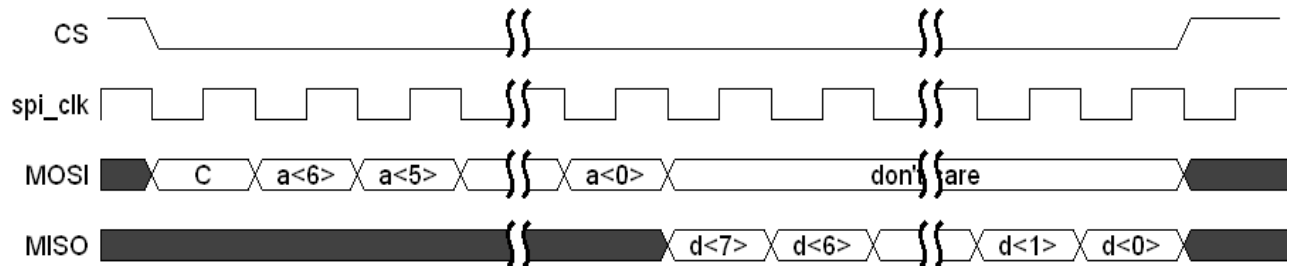
Disable Sequencer → Upload through SPI → ENable Sequencer

Read Sequence, C=0

The part is selected by pulling CS low. The 1-bit instruction (READ) is transmitted to the image sensor, followed by the 7-bit address (A6 through A0). The instruction and address bits are clocked in on the rising edge of the clock. After the correct READ instruction and address are sent, the data stored in the memory at the selected address is shifted out on the MISO pin. The data bits are shifted out on the first falling edge after the last address bit is clocked. The read operation is terminated by raising the CS pin. The maximum operating frequency is 10 MHz.

Note SPI settings cannot be uploaded during readout.

Figure 14. SPI Read Timing



Write Sequence, C=1

The image sensor is selected by pulling CS low. The WRITE instruction is issued, followed by the 7-bit address, and then the 8-bit data. All data is clocked in on the rising edge of the clock.

To write the data to the array, the CS is brought high after the least significant bit (D0) of the data byte is clocked in. If CS is brought high at any other time, the write operation is not completed. Maximum operating frequency is 10 MHz.

Figure 15. SPI Write Timing

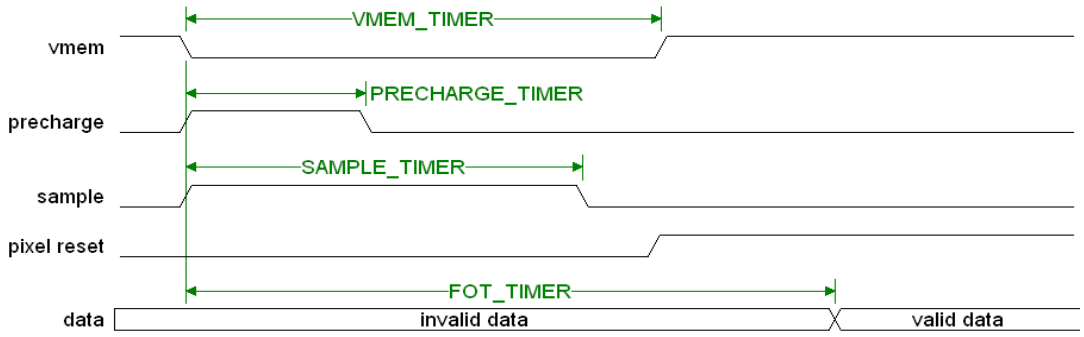
Image Sensor Timing and Readout

Pixel Timing

After every exposure cycle, the value on the pixel diode is transferred to the pixel storage capacitor. This is controlled by Vmem, precharge, and sample signals. The duration of this operation is the Frame Overhead Time (FOT). At the beginning of the FOT, Vmem is brought low, and precharge and sample are brought high. The precharge pulse ensures that the old information on the storage node is destroyed. This ensures there is no image lag. After the falling edge of the precharge pulse, the sampling operation on the storage node is completed during the high level of sample.

After the falling edge of sample, Vmem is brought high. The rise in Vmem compensates for the voltage loss in the last source follower in the pixel. The readout begins after this. The pulse length is controlled by the user. The registers that control this are listed in the following section.

Figure 16. Pixel Timing



Considerations in Pixel Timing

The length of the FOT_TIMER, PRECHARGE_TIMER, and SAMPLE_TIMER influences the final image quality.

- Precharge pulse: The pixel precharge prevents image lag. A very short pulse results in image lag.
- Sample pulse: A shorter sample results in a reduced dark level.
- FOT_TIMER register: The vmem signal must charge all pixel storage capacitors simultaneously. This is a large combined capacitance (96 nF) and Vmem takes some time to stabilize. Readout must start only after Vmem is stable.

The length of pixel_reset influences image lag. The pixel must be reset for at least 3 µs.

Frame Rate and Windowing

Frame Rate

The frame rate depends on the input clock, the frame overhead time (FOT), and the row overhead time (ROT). The frame period is calculated as follows:

1 kernel = 32 Pixels

1 Gran. Clock = 4 clock periods

Table 45. Clarification of Frame Rate Parameters

Parameter	Comment	Clarification
FOT	Frame Overhead Time	The FOT does a frame transfer from pixel diode to the pixel storage node. During this transfer period, the sensor is not readout. The FOT length is programmable. The default length is 3.2 µs.

Table 45. Clarification of Frame Rate Parameters

Parameter	Comment	Clarification
ROT	Row Overhead Time	The ROT transfers the pixel output to the column amplifiers. Default ROT is 176 ns.
Nr. Lines	Number of lines readout each frame	Default is 1710 lines.
Nr. Pixels	Number of pixels readout each line	Default is 1696 pixels.
Data Period	0.5 x Clock period = 2.427 ns	Because the outputs operate at DDR, the data period is half the clock period (206 MHz clk).

Frame period = FOT + Nr. Lines * (ROT + Nr. Pixels/4 * Data Period)

Or

Frame period = FOT + Nr. Lines * (ROT + Nr. kernels * Granularity Clock cycles)

Example

Readout time for full resolution at nominal speed of 206 MHz (4.854 ns) is given by

Frame Period = 3.2 µs + (1710 * (176 ns + 1696/4*2.427ns)) = 2.063 ms

Or

Frame Period = 3.2 µs + (1710 * (176 ns + 53*19.4174ns)) = 2.063 ms

Frame Rate =485 FPS

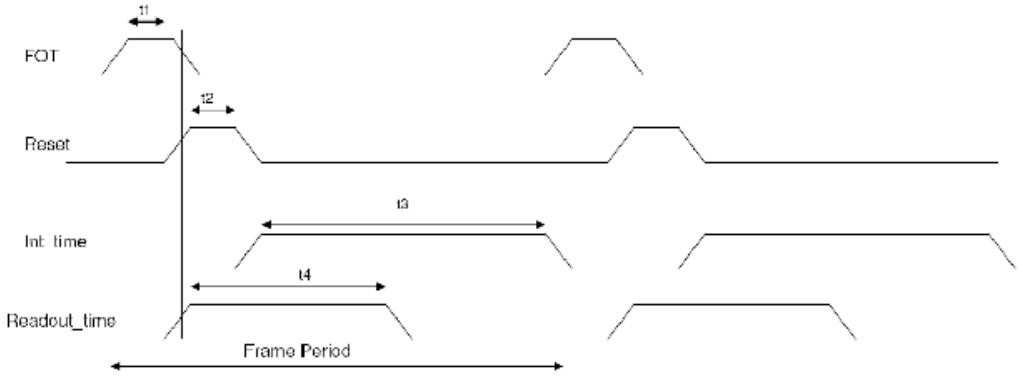
Alternatively, frame rate can also be expressed in terms of reset length and Integration time rather than readout time.

The sequence of events shown in Figure 17 occurs during integration and readout in pipelined global shutter mode.

Downloaded from Elcodis.com electronic components distributor

[+] Feedback

Figure 17. Timing Diagram



Frame Period = FOT + Reset length + Integration time

= t1+t2+t3

To receive the frames without any overlap, the summation of reset time and integration time should always be greater than the readout time.

(Reset time + Integration time) > Readout time

Note For more information, refer the Cypress application note AN57864.

In global shutter mode, the whole pixel array is integrated simultaneously.

Windowing

Windowing is easily achieved by SPI. The starting point of the x and y address and the window size can be uploaded. The minimum step size is in the x direction is 32 pixels (choose only multiples of 32 as a start or stop addresses). The minimum step in the y direction is 1 line (every line can be addressed in the normal mode).

Table 46. Typical Frame Rates at 206 MHz

Image Resolution (X*Y)	Frame Rate (fps)	Frame Period(ms)
1696 x1710	484	2.065
1600 x 1200	712	1.404
1280 x 1024	1001	1.000
640 x 480	2653	0.377
512 x 512	3808	0.263
256 x 256	10704	0.093
128 x 128	26178	0.038

Operation and Signaling

Digital Signals

LUPA 3000 operates in slave mode; the pixel array of the image sensor requires different digital control signals. The function of each signal is listed in Table 47..

Table 47. Overview of Digital Signals

Signal Name	I/O	Comments
FOT	Output	Output pin for FOT
ROT	Output	Output pin for ROT
Exposure_2	Input	Integration pin dual slope
Exposure_1	Input	Integration pin first slope
RESET_N	Input	Sequencer reset, active LOW
CLK	Input	System clock (206 MHz)
SPI_CS	Input	SPI chip select
SPI_CLK	Input	SPI clock
SPI_MOSI	Input	Data line of the SPI, serial input
SPI_MISO	Output	Data line of the SPI, serial output

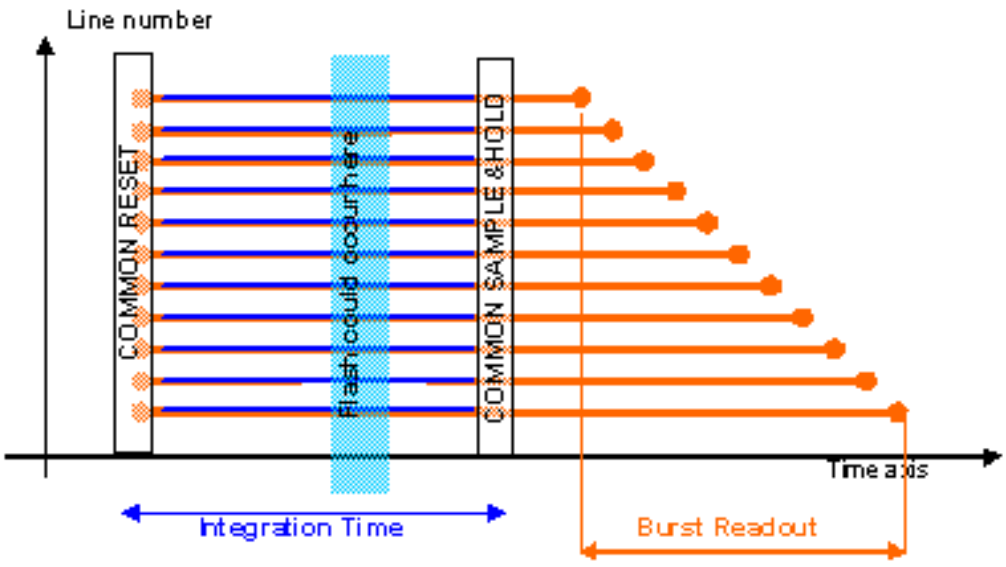
Global Shutter Mode

In a global shutter, light integration occurs on all pixels in parallel, although subsequent readout is sequential. Figure 18 shows the integration and readout sequence for the global shutter. All pixels are light sensitive at the same period of time. The whole pixel core is reset simultaneously, and after the integration time, all pixel values are sampled together on the storage node inside each pixel. The pixel core is read out line by line after integration.

Note that the integration and readout cycle can occur in parallel or in sequential mode (pipelined or triggered).

Figure 18. Global Shutter Operation

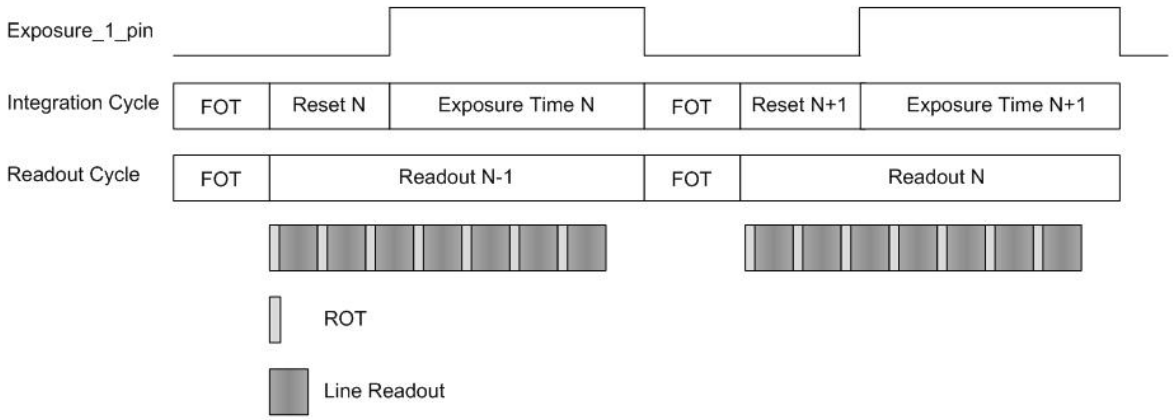


Global Pipeline Shutter

The timing of the sensor consists of two parts. The first part is related to the exposure time and the control of the pixel. The second part is related to the read out of the image sensor. Integration and readout are in parallel or triggered. In the first case, the integration time of frame I is ongoing during the readout of frame I-1. Figure 19 shows this parallel timing structure.

The readout of every frame starts with a FOT, during which the analog value on the pixel diode is transferred to the pixel memory element. After this FOT, the sensor is read out line by line. The read out of every line starts with a ROT, during which the pixel value is put on the column lines. The pixels are selected in groups of 32 (kernel). The internal timing is generated by the sequencer. LUPA3000 works in slave mode, the integration timing is directly controlled over two external pins (Exposure 1 and Exposure 2) but the readout timing is still controlled by the sequencer.

Figure 19. Global Readout Timing



Downloaded from Elcodis.com electronic components distributor

[+] Feedback

The integration time is controlled by the external Exposure 1 pin. The relationship between the input pin and the integration time is shown in Figure 19. When the input pin Exposure 1 is asserted, the pixel array goes out of reset and exposure can begin. When Exposure 1 goes low again and the desired exposure time is reached, the image is sampled and read out can begin.

Global Triggered Shutter

Integration starts as soon as exposure1_pin is asserted. When exposure1_pin goes low, FOT occurs followed by read out. The sensor is kept in reset until exposure1_pin goes high again. .

The possible applications for this triggered shutter mode are:

- Synchronize external flash with exposure
- Apply extremely long integration times

Figure 20. Integration and Readout for Triggered Shutter

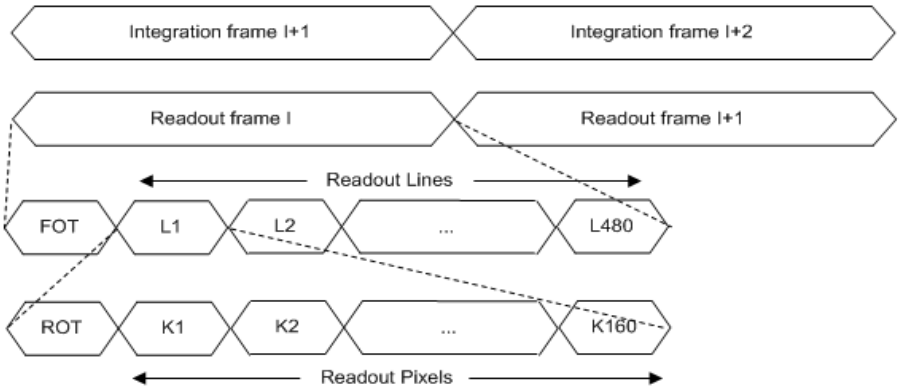
Timing and Readout of the Sensor

High Level Timing

The LUPA 3000 sensor is a pipelined synchronous shutter. This indicates that light integration and readout occur in parallel, achieving the high frame rate and data throughput.

The maximum frame rate of the sensor is determined by the time needed to readout a full frame. This frame time is separated in the FOT and the time to readout all lines. The readout of a line is separated in a ROT and the readout of all kernels.

Figure 23. Pipelined Operation



Integration Timing

The integration time is controlled through the EXPOSURE_1 pin. The rising edge of EXPOSURE determines the start of exposure and the falling edge of EXPOSURE_1 starts the FOT and determines the end of the integration time.

The falling edge of the internal pixel reset pulse causes a visible crosstalk in the image, unless the edge occurs in the beginning of the ROT during readout. As a result, the EXPOSURE pulse is internally delayed until the next ROT. The duration of this delay depends on the length of the line being readout. If the EXPOSURE_1 is after Lx is finished, then integration starts immediately. There is no need to wait for ROT.

The internal timing of the FOT is controlled by the sequencer. The length of the FOT is set by the SPI registers PRECHARGE_TIMER, SAMPLE_TIMER, VMEM_TIMER, and FOT_TIMER.

Ensure that pixel_reset is high for at least 3 µs.

FOT Starts After Readout

This is the normal situation where a full window is readout. A full window refers to the resolution set by the Y_START, Y_END, and NB_OF_KERNELS register. This may be the full resolution or a partial window. Figure 24 shows a high level timing; ‘Lx’ refers to ‘line x’.

When EXPOSURE_1 goes low, the FOT begins immediately. Integration time continues until the falling edge of pix_sample. The falling edge of pix_sample is a fixed amount of time after the falling edge of EXPOSURE_1. This time is set SAMPLE_TIMER (see Frame Overhead Time).

Figure 24. High Level Readout Timing

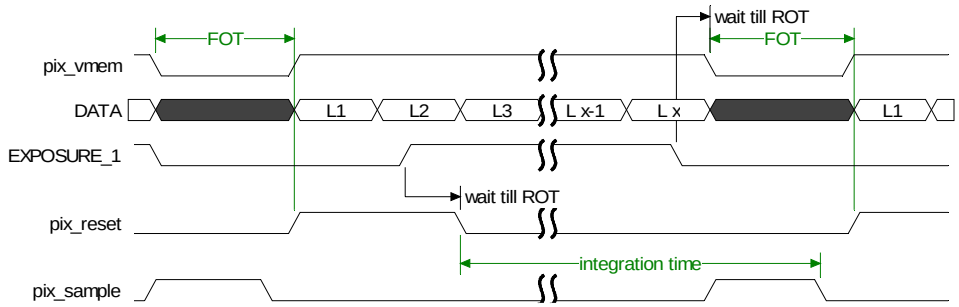
[+] Feedback

FOT Starts Before Readout

When the EXPOSURE_1 signal goes low before the window readout has finished, the readout is interrupted after the completion of the current line's readout (line x in Figure 25).

Figure 25. High Level Readout Timing



Dual Slope Integration Timing

If the dual slope enable bit is set high, dual slope integration is controlled through the EXPOSURE_2 pin. If the dual slope enable bit is set low, the dual slope integration is disabled.

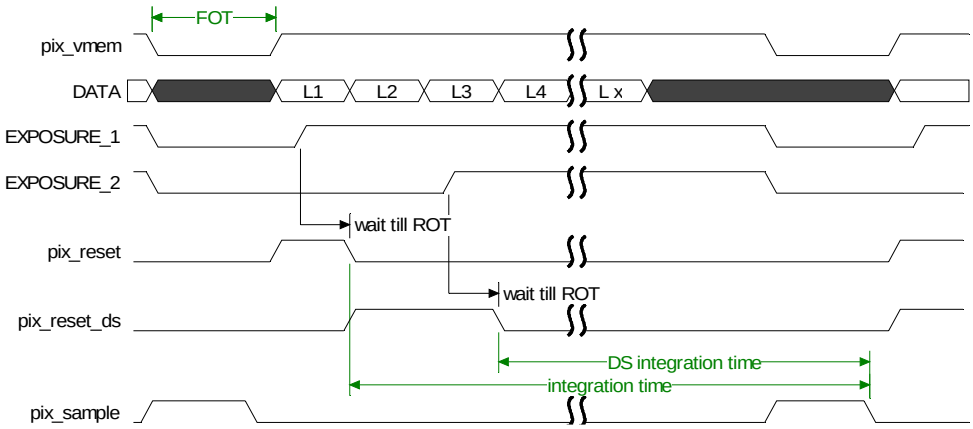
Figure 26 shows the timing. The pix_reset signal is controlled by the EXPOSURE_1 pin. When pix_reset goes low, the dual slope reset of the pixel array is activated. Bringing the EXPOSURE_2 pin high starts the dual slope integration.

The start of the FOT is controlled by the falling edge of the EXPOSURE_1 pin. The EXPOSURE_2 pin must be brought low during FOT to be ready for the next cycle.

Setup and Hold Requirements

EXPOSURE_1 and EXPOSURE_2 are deglitched using two chained flipflops that clock on the sensor clock. As a result, there is no setup requirement for both signals relative to LVDS_CLKIN. The hold requirement is 15 clock periods of LVDS_CLKIN.

Figure 26. Dual Slope Integration Timing



Readout Modes

The sensor is configured to operate in three readout modes: training, test image readout, and normal readout. These modes enable correct communication between the sensor and the customer system.

Readout of Training Sequence

By setting the TRAINING_EN and BYPASS_MODE bit, all data channels and the sync channel transmit alternating the Idle_A and Idle_B word. Rotating the received Idle_A and Idle_B words in the receiver allows correcting for skew between the LVDS outputs and the receiver clock. The Idle_A and Idle_B words are programmed by the user.

Readout of Test Image

By setting the BYPASS_MODE bit high and the TRAINING_EN bit low, the sensor is configured to output a programmable test pattern.

The sync channel operates as in normal readout and enables frame and line synchronization. Every data channel transmits a fixed, programmable word to replace normal data words coming from the ADC. In this mode, the sensor behaves as in normal readout. The sync channel transmits programmable keywords to allow frame and line synchronization. When not transmitting data from the ADC, the data channels transmit the toggling Idle_A and Idle_B words. As a result, the data stream from the sensor has a fixed format.

[+] Feedback

Data Stream

Figure 27 represents the data stream of the data and control channels. Data channel “i” outputs the data from column “i” of every kernel. All control words in Table 48 can be uploaded through the SPI.

A SOF word is followed by an EOL word, as shown in Figure 27 This misplaced EOL word is ignored. The CRC is valid during transmission of the test image.

Normal Readout Mode

In normal readout mode, the data channels transmit data coming from the ADCs. The sync channel operates as described in the section Readout of Test Image on page 40. The data stream shown in Figure 27 is still valid.

Figure 27. Timing of Data Stream

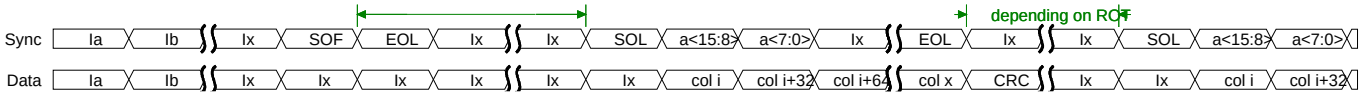

Table 48. Control Words Transmitted Over Sync Channel

Keyword	Description
Ia	Idle word A
Ib	Idle word B
Ix	Idle word A or idle word B
SOF	Start of frame
SOL	Start of line
EOL	End of line
a<15:8>	Address of line being readout, a<15> is the MSB
a<7:0>	Address of line being readout

Frame Overhead Time

The FOT is controlled by the PRECHARGE_TIMER, SAMPLE_TIMER, VMEM_TIMER, and FOT_TIMER SPI registers. Typical values are:

- PRECHARGE_TIMER: 1.5 us
- SAMPLE_TIMER: 2.5 us
- VMEM_TIMER: 2.7 us
- FOT_TIMER: 3.2 us

FOT_TIMER provides the moment when the signal sampled in the pixel is stable and ready for readout. FOT_TIMER arrives typically 500 ns after VMEM_TIMER. The rising edge of pixel_reset coincides with the rising edge of pixel_vmem.

Figure 28. FOT Timing

[+] Feedback

Reduced ROT Readout Mode

After selecting a pixel row, the pixels need to charge a large capacitive load. This load is caused by the long metal line connecting all the pixels of a column and by the number of pixels that are connected to this line. As a result, it takes a long time to charge this line. The column load transistors act as a current source that is a load to the source follower inside the pixel. If the current source draws more current, the settle time on the columns is faster. However, the drawback is a higher power dissipation of the 1696 column in parallel.

In reduced ROT mode, the settle time on the columns are limited by using the large capacitive load of the column itself as a sampling capacitor. The column load current is not needed any more and the rise time on the columns is shorter. By going to a very short ROT (100-120 ns), the dynamic range becomes less. By going to a normal ROT, the dynamic range becomes equal or larger than in non reduced ROT mode, and the power consumption is less.

The sensor operates in reduced ROT by default, with a ROT of nine sensor clock periods (175 ns).

FOT and ROT Pin Timing

The chip has two pins (FOT and ROT) that indicate internal FOT and ROT periods.

FOT Pin

The actual FOT goes from the falling edge of the internal VMEM signal to the rising edge of the first internal CLK_Y. After this rising edge of CLK_Y, the first ROT starts. The FOT pin goes high at the same moment VMEM goes low and remains high until one sensor clock period (CLKIN/4) before the end of the actual FOT. This is shown in Figure 29.

ROT Pin

The actual ROT goes from the rising edge of the internal CLK_Y signal to the falling edge of the internal SYNC_X signal. The ROT pin goes high at the rising edge of CLK_Y and remains high until one sensor clock (CLKIN/4) before the end of the actual ROT.

Table 49. FOT and ROT Pin Timing

Pin	Delay vs. Sensor Clock	Rise and Fall Times (20 pF Load)
FOT	2.5 ns	6 ns
ROT	2.5 ns	6 ns

Figure 29. FOT Pin Timing

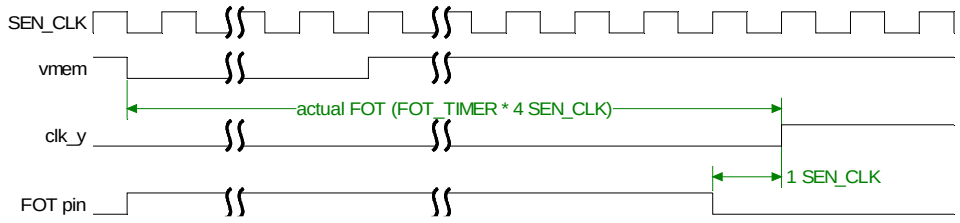

Figure 30. ROT Pin Timing

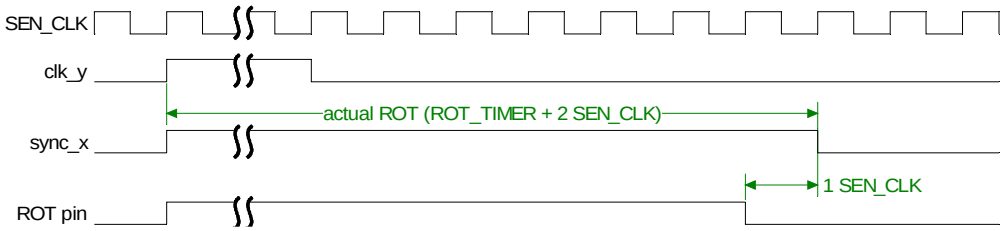


Asynchronous Reset

The sensor has a reset pin, RESET_N, and a reset SPI register, RESET_N_SEQ. Both are active low.

RESET_N is the chip reset. All components on the chip are reset when this pin is low. This includes the sequencer, the SPI register, and X and Y shift registers. The reset is asynchronous.

RESET_N_SEQ is the sequencer reset. Bringing this bit low only resets the sequencer. This is used to restart the sequencer with the current SPI settings.

Reset on Startup

When the sensor starts up, RESET_N is kept low until all supply voltages are stable. After the rising edge of RESET_N, RESET_N_SEQ is kept low for an additional 0.5 µs.

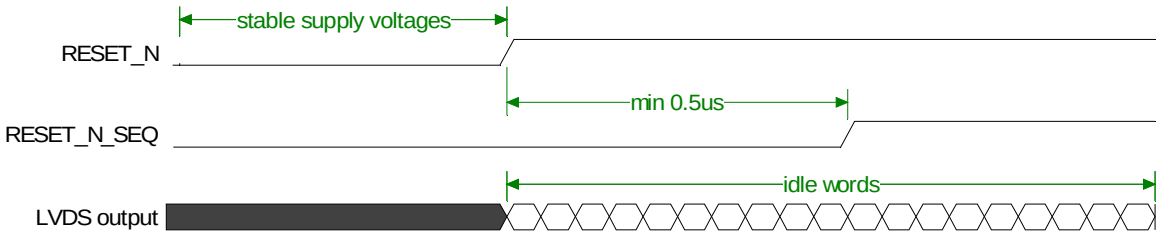
During the chip reset the data on the LVDS outputs (data channels and sync channel) is invalid. When the chip comes out of reset, but the sequencer is kept in reset, the LVDS outputs toggle between the idle words.

Downloaded from Elcodis.com electronic components distributor

[+] Feedback

If RESET_N_SEQ is only low for a short period of time (100 ns), the pixel array is not completely reset. Information from the previous integration cycle is still present on the photodiode. Ensure that the pixels are in reset for at least 3 µs by keeping RESET_N_SEQ low for a long time, or by not starting exposure before 3 µs after RESET_N_SEQ.

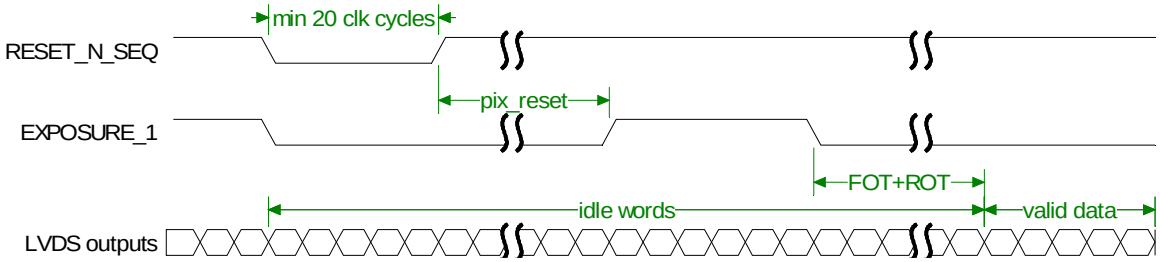
Figure 31. Reset on Startup



Sequencer Reset

The sequencer is reset separately by bringing the RESET_N_SEQ register low. This causes an asynchronous reset of the sequencer. The reset must have a length of at least 20 clock cycles (five words). Resetting the sequencer corrupts the analog voltages stored in the pixel array. Therefore, a new readout sequence must start with an exposure first. After the reset, a readout sequence is reinitiated by using EXPOSURE_1 pin. Ensure the reset of the pixel array is long enough (>= 3 µs).

Figure 32. Sequencer Reset



Startup Sequence

To guarantee the correct startup of all the sensor modules, perform the following startup sequence:

1. All supplies are powered on simultaneous, but the RESET_N pin is kept low. The VAA is not powered on before VDD is powered on.
2. When all supplies are stable, bring RESET_N pin high. The sensor now begins to operate.
3. Set RESET_N_SEQ register bit to zero if other SPI registers need to be uploaded.
4. Set the RESET_N_SEQ bit to 1 if all required SPI registers are changed. LUPA 3000 operates only in slave mode; therefore, the sensor is now controlled through the EXPOSURE_1 pin.

Additional Features

Windowing

A fully configurable window can be selected for readout. The parameters to configure this window are:

X_START: It is the start position for the X readout. Readout starts only at odd kernel positions. As a result possible start positions are 64 columns (two kernels) separated from each other.

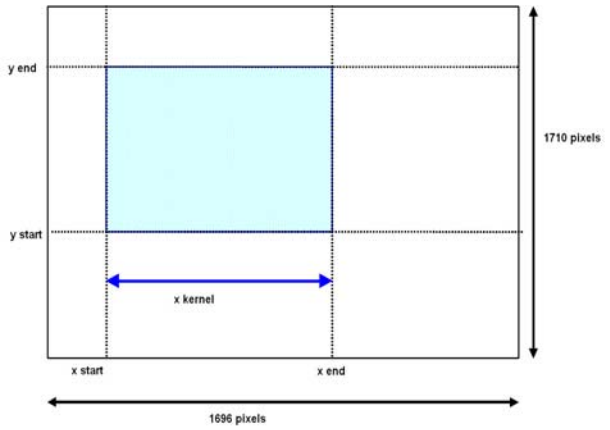
X_kernels: The number of kernels to be readout.

Y_start: The starting line of the readout window.

Y_end: The end line of the readout window, granularity of 1.

For windowing, the effective readout time is smaller than in full frame mode, because only the relevant part of the image array is accessed. As a result, it is possible to achieve higher frame rates.

Figure 34. Window Selected for Readout



Restrictions to Windowing

To ensure correct operation of the sensor the readout of partial windows must be done with some restrictions.

- The minimum window size is 4 kernels (128 pixels) in the X direction and 1 line in the Y direction.
- In the X direction windowing can only start at an odd kernel (kernel1, kernel3, …). Then number of kernels to readout is not subject to an odd-even restriction.
- The sum of the ROT_TIMER and the NB_OF_KERNELS spi registers should always be an even number.

This means that for a fixed ROT time, the window size can only change in steps of 64 pixels. If the number of kernels to readout is decreased with one and the ROT is already at the minimum value, then the ROT time should be incread with one (clock cycle) to compensate. The framerate remains unchanged by this, but the data rate drops.

Sub Sampling

Reverse Scan

Not supported by LUPA 3000

Multiple Windows

Not supported by LUPA 3000

Multiple Slopes

Dynamic range can be extended by the multiple (dual) slope capability of the sensor. The four colored lines in Figure 35 represents analog signals of the photodiode of four pixels, which decreases as a result of exposure. The slope is determined by the amount of light at each pixel (the more light, the steeper the slope). When the pixels reach the saturation level, the analog does not change despite further exposure. Without the multiple slope capabilities, the pixels p3 and p4 are saturated before the end of the exposure time, and no signal is received. However, when using multiple slopes, the analog signal is reset to a second reset level (lower than the original) before the integration time ends. The analog signal starts decreasing with the same slope as before, and pixels that were saturated before could be nonsaturated at read out time. For pixels that never reach any of the reset levels (for example, p1 and p2) there is no difference between single and multiple slope operation.

By choosing the time stamps of the double slope resets (typical at 90%, configurable by the user), it is possible to have a nonsaturated pixel value even for pixels that receive a huge amount of light.

The reset levels are configured through external (power) pins.

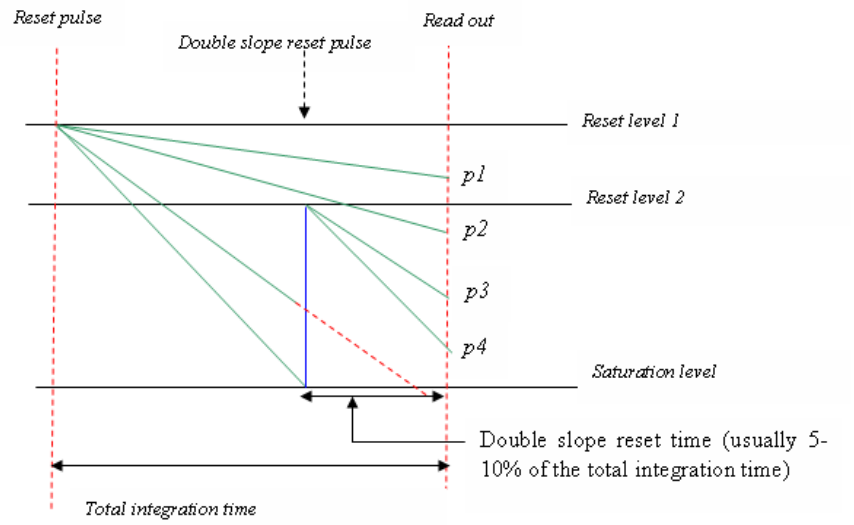
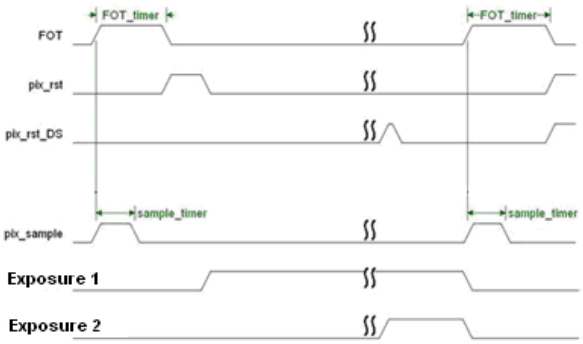
Figure 35. Dynamic Range Extended by Multiple Slope Capability



In slave mode, you have full control through the pins Exposure 1 and Exposure 2. You must configure the multiple slope parameters for the application and interpret the pixel data accordingly.

Figure 36. Dual Slope Timing in Slave Mode



Off Chip FPN correction

FPN is a kind of spatial noise, a noise that does NOT change with time.FPN comes from two different sources. The first source involves the variations between individual pixels. Within a CMOS image sensor, the device is designed such that each pixel is exactly similar to all the others.

Although each pixel is very similar to all of the others within the array, there are slight variations. These variations arise from variations in threshold voltages and offsets of the amplifier within each pixel. Because these can vary for each pixel within the pixel array; they are referred to as Pixel FPN.

The second source of FPN involves the performance variations of the amplifiers shared by each column of the pixel array. The information within the pixel array is read out on a column-by-column basis through these column amplifiers. When one amplifier behaves slightly different from another, the entire column can be affected. When this happens, it results in what appears to be vertical lines in the image. This is commonly called Column FPN. Of the two sources of FPN, column FPN is far more noticeable than pixel FPN.

Note LUPA 3000 has no on-chip FPN correction so it has to be corrected off-chip in the software.

FPN can be calibrated off chip by subtracting a dark image from all captured images. For optimal results two guidelines can be followed:

- Use an averaged dark image to calibrate FPN, this eliminates other noise sources that would be present in the dark image.
- Use a different dark image to calibrate for different operation conditions. Different operation conditions can be changes in temperature, FOT and ROT timing, and gain settings.

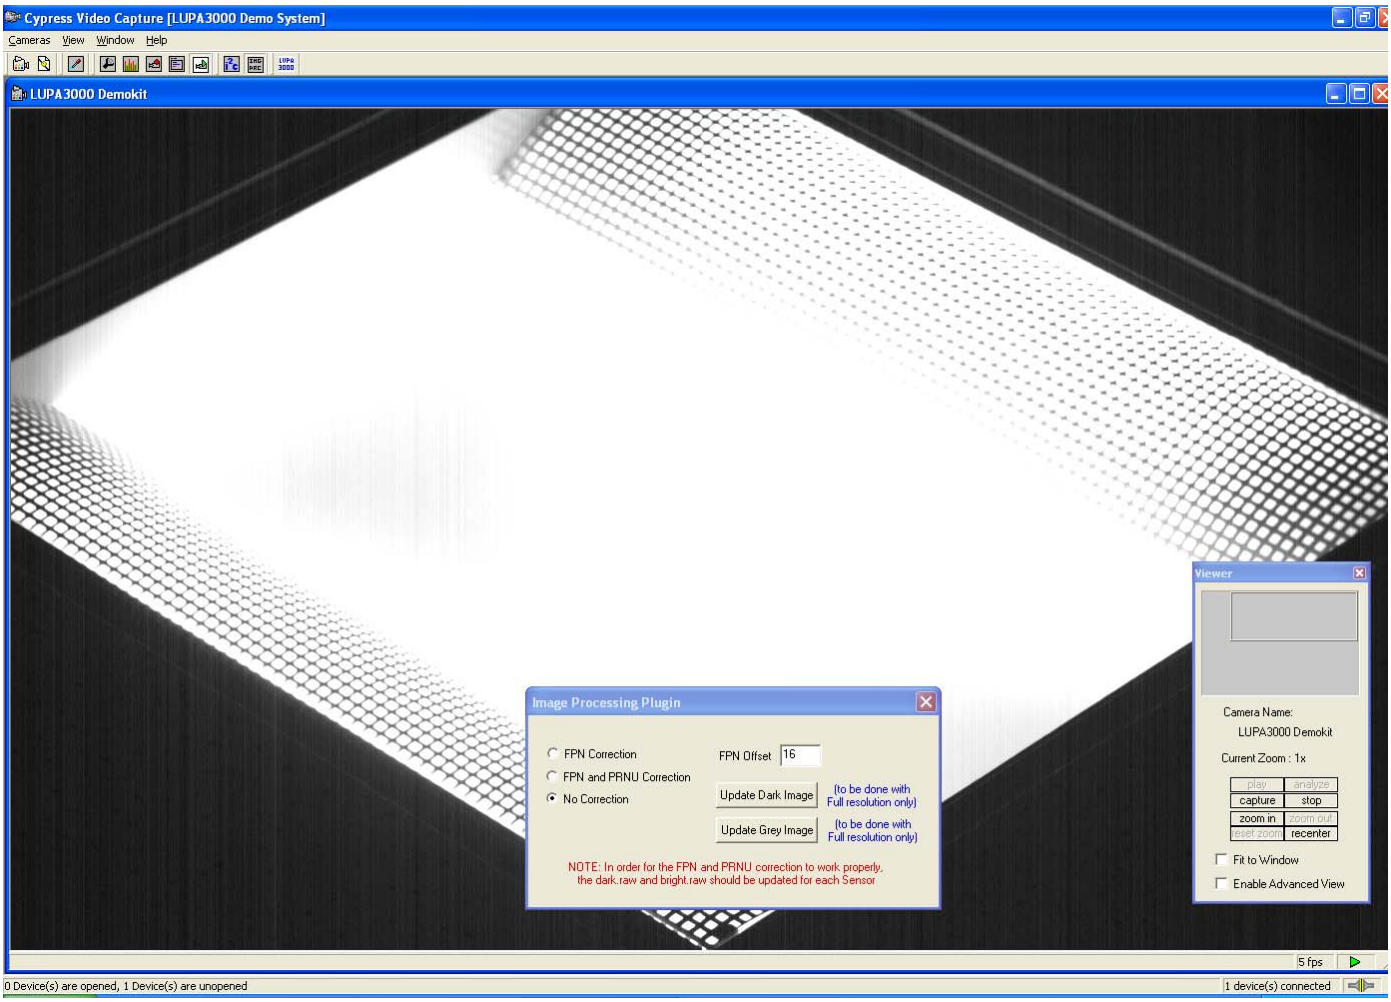
[+] Feedback

Figure 37. Normal Image without FPN and PRNU Correction.



The fpn lines can be seen clearly in the darker and bright regions of the image.

Software FPN Correction

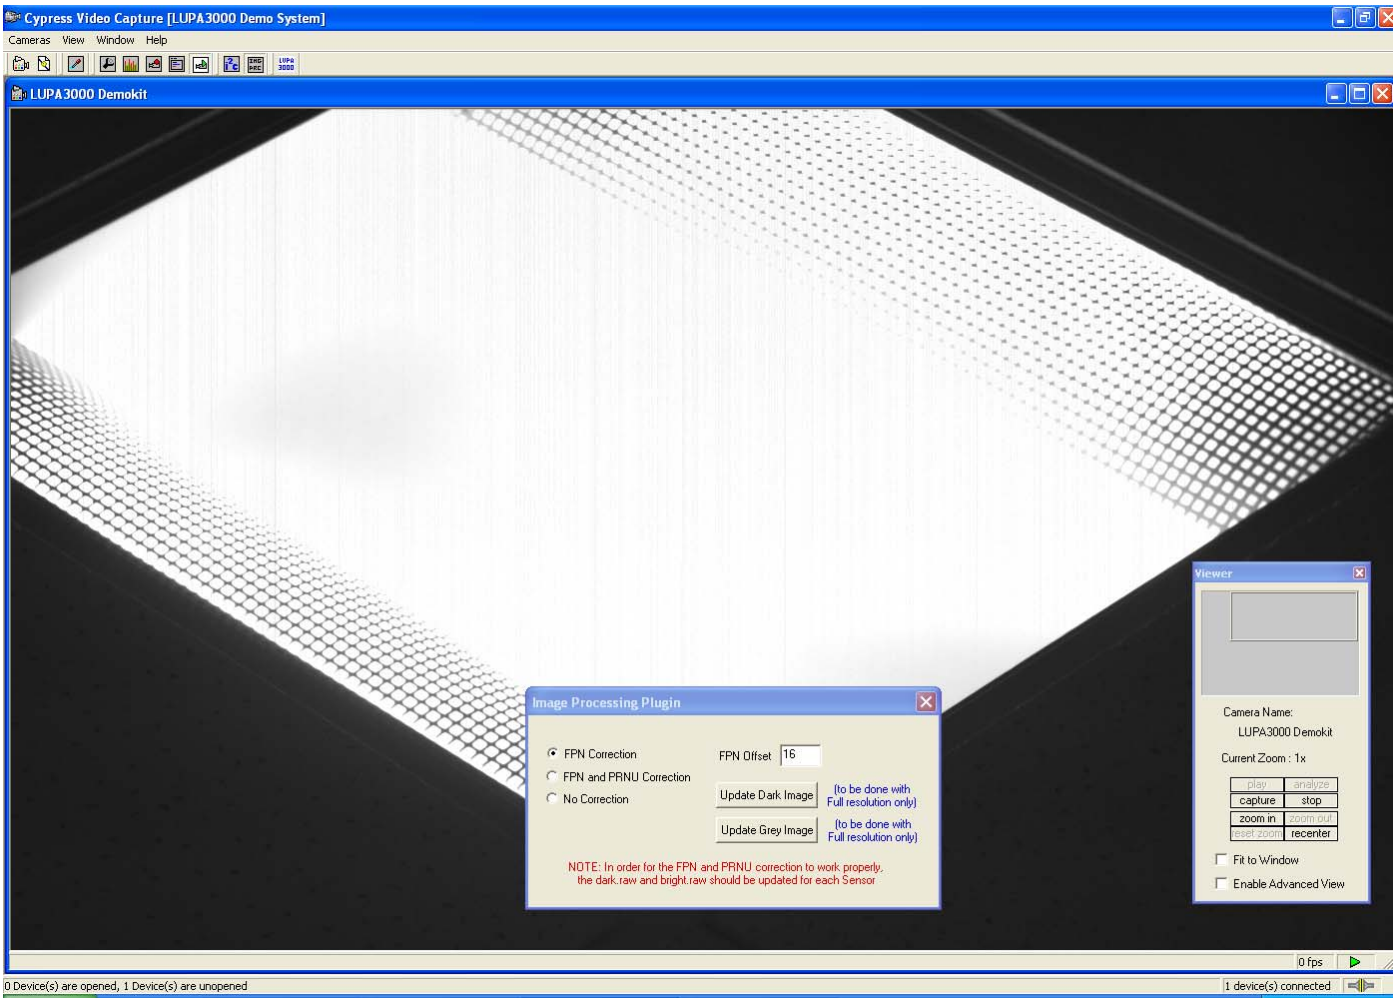
The procedure is as follows:

1. Adjust the black level with the help of histogram by modifying DAC offset.
2. Store a dark image by closing the lens aperture, but make sure no value is absolute zero.
3. Subtract the dark reference image from all the captured images.

Downloaded from Elcodis.com electronic components distributor

[+] Feedback

Figure 38. Image with FPN Correction



The fpn lines in the darker regions are no longer present.

However at an angle, fpn lines can be seen in the brighter region as marked in the image. These lines in the brighter regions can be eliminated by applying PRNU correction as explained here.

Note that PRNU correction should be applied along with FPN correction, it cannot be applied individually.

Off Chip PRNU Correction

Pixel Response Non-uniformity (PRNU) is also a kind of spatial noise and it refers to the slight variations in response to the same input that each pixel has due to the slight active response variations between the amplifiers within different pixels. Even though every pixel is carefully designed to match one another, slight variations in processing, noise, and other areas can cause these amplifiers to behave differently.

This is corrected with the help of a grey image and the correction is done by equalization of gain.

The procedure is as follows:

1. Capture the grey image under the same condition as the dark image.
2. Open the aperture of the lens to allow light and then capture the grey frame. All the pixels in the grey image should have a grey value of approximately 70% white (histogram should peak at 70% white and the distribution should be uniform around the peak as much as possible). This grey image is stored.

FPN and PRNU correction formula:

Vn = (Avg(Wn) / [Wn - Bn + 1]) x (Gn - Bn)

Vn - data of a pixel after a calibration

Gn - data of a pixel before carrying out a calibration

Bn - black calibration data of the pixel

Wn - white (Gray) calibration data of the pixel

The image with both FPN and PRNU correction is shown in Figure 39. Note that no FPN lines are present in this image even in saturated regions.

Table 50. Pin List

Finger Number	Pin Number	Function	Description
212	D7	GNDd	Ground digital
213	C7	Vadc	2.5 V ADC
214	B7	GNDadc	Ground ADC
215	C6	Vadc	2.5 V ADC
216	B6	GNDadc	Ground ADC
217	D6	Vdd	2.5 V digital
218	D5	GNDd	Ground digital
219	C5	Vadc	2.5 V ADC
220	B5	GNDadc	Ground ADC
221	A6	Vrefp	Decoupling analog reference voltage
222	A5	Vrefm	Decoupling analog reference voltage
223	B4	Vdd_hs	2.5 V high speed digital
224	A4	GNDd_hs	Ground high speed digital
225	F6	D/A Ground	Die attach ground
226	R6	D/A Ground	Die attach ground
227	T19	D/A Ground	Die attach ground
228	E20	D/A Ground	Die attach ground

Pin Assignment

Die Attach Ground Pins

The pins listed as die attach pins should be connected to the PCB ground plane or to an active cooling device.

Non Assigned Pins

Pins that are marked “not assigned” in the pin list must be left floating. Some of them are used by Cypress for debugging.

Mechanical Specifications

Table 51. Mechanical Specifications

Mechanical Specifications		Min	Typ	Max	Units
Die (Referenced to Pin 1 being bottom left in Figure 41 on page 58)	Die thickness		750		µm
	Die center, X offset to the center of package		0		µm
	Die center, Y offset to the center of the package		0		µm
	Die position, X tilt	-1	0	1	deg
	Die position, Y tilt	-1	0	1	deg
	Die placement accuracy in package	-50	0	50	um
	Die rotation accuracy	-1	0	1	deg
	Optical center referenced from the package center.		-230		µm
	Optical center referenced from the package center.		1450		µm
	Distance from PCB plane to top of the die surface		2		mm
	Distance from top of the die surface to top of the glass lid		2		mm
Glass Lid Specification	X * Y size		28.2 x 19.5		mm
	Thickness		1		mm
	Spectral range for optical coating of window	400		1100	nm
	Reflection coefficient for window			<0.8	%
Mechanical shock	JESD22-B104C; Condition G		2000		G
Vibration	JESD22-B103B; Condition 1	20		2000	Hz
Mounting Profile	Lead-free wave soldering profile for pin grid array package if no socket is used				
Recommended socket manufacturer	Andon Electronics (http://www.andonelectronics.com)	BGA Socket: 10-21-06-369-414T4-R27-L14			
		Thru Hole: 10-21-06-369-400T4-R27-L14

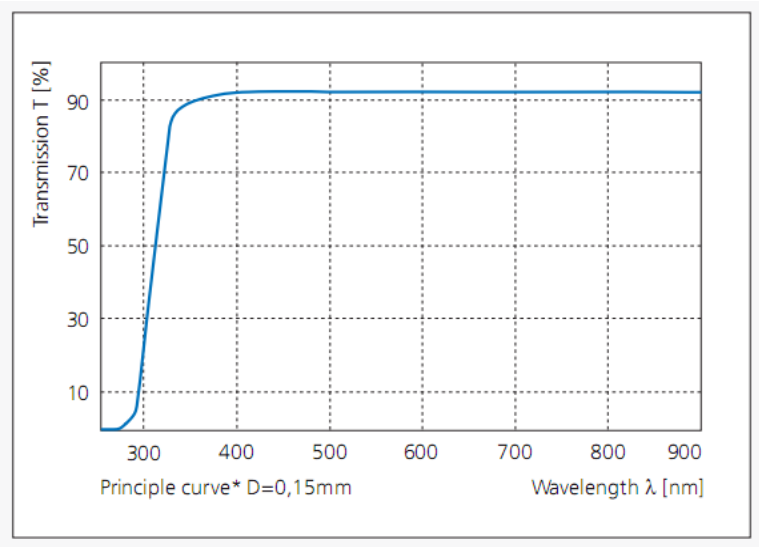
Glass Lid

The LUPA 3000 image sensor uses a glass lid without any coatings. Figure 43 shows the transmission characteristics of the glass lid.

As seen in Figure 43, no infrared attenuating color filter glass is used. A filter must be provided in the optical path when color devices are used. (source: http://www.pgo-online.com).

Figure 43. Transmission Characteristics of the Glass lid



Handling Precautions

For proper handling and storage conditions, refer to the Cypress application note AN52561 at www.cypress.com.

Limited Warranty

Cypress Image Sensor Business Unit warrants that the image sensor products to be delivered hereunder if properly used and serviced, will conform to Seller's published specifications and will be free from defects in material and workmanship for one (1) year following the date of shipment. If a defect were to manifest itself within 1 (one) year period from the sale date, Cypress will either replace the product or give credit for the product.

Return Material Authorization (RMA)

Cypress packages all of its image sensor products in a clean room environment under strict handling procedures and ships all image sensor products in ESD-safe shipping containers. Products returned to Cypress for failure analysis should be handled under these same conditions and packed in its original packing materials, or the customer may be liable for the product.

Sales, Solutions, and Legal Information

Worldwide Sales and Design Support

Cypress offers standard and customized CMOS image sensors for consumer as well as industrial and professional applications. Consumer applications include solutions for fast growing high speed machine vision, motion monitoring, medical imaging, intelligent traffic systems, security, and barcode applications. Cypress's customized CMOS image sensors are characterized by very high pixel counts, large area, very high frame rates, large dynamic range, and high sensitivity.

Cypress maintains a worldwide network of offices, solution centers, manufacturer's representatives, and distributors. For more information on Image sensors, contact imagesensors@cypress.com.
