

The MPC9446 is a 2.5 V and 3.3 V compatible 1:10 clock distribution buffer designed for low-voltage mid-range to high-performance telecom, networking and computing applications. Both 3.3 V, 2.5 V and dual supply voltages are supported for mixed-voltage applications. The MPC9446 offers 10 low-skew outputs and 2 selectable inputs for clock redundancy. The outputs are configurable and support 1:1 and 1:2 output to input frequency ratios. The MPC9446 is specified for the extended temperature range of -40°C to 85°C .

Features

- Configurable 10 outputs LVCMOS clock distribution buffer
- Compatible to single, dual and mixed 3.3 V/2.5 V voltage supply
- Wide range output clock frequency up to 250 MHz
- Designed for mid-range to high-performance telecom, networking and computer applications
- Supports applications requiring clock redundancy
- Maximum output skew of 200 ps (150 ps within one bank)
- Selectable output configurations per output bank
- Tristable outputs
- 32-lead LQFP package
- 32-lead Pb-free package available
- Ambient operating temperature range of -40 to 85°C

Functional Description

The MPC9446 is a full static fanout buffer design supporting clock frequencies up to 250 MHz. The signals are generated and retimed on-chip to ensure minimal skew between the three output banks. Two independent LVCMOS compatible clock inputs are available. This feature supports redundant clock sources or the addition of a test clock into the system design. Each of the three output banks can be individually supplied by 2.5 V or 3.3 V supporting mixed voltage applications. The FSELx pins choose between division of the input reference frequency by one or two. The frequency divider can be set individually for each of the three output banks. The MPC9446 can be reset and the outputs are disabled by deasserting the MR/ $\overline{\text{OE}}$ pin (logic high state). Asserting MR/ $\overline{\text{OE}}$ will enable the outputs.

All inputs accept LVCMOS signals while the outputs provide LVCMOS compatible levels with the capability to drive terminated $50\ \Omega$ transmission lines. Please consult the MPC9456 specification for a 1:10 mixed voltage buffer with LVPECL compatible inputs. For series terminated transmission lines, each of the MPC9446 outputs can drive one or two traces giving the devices an effective fanout of 1:20. The device is packaged in a $7 \times 7\ \text{mm}^2$ 32-lead LQFP package.

Table 1. Pin Configuration

| Pin | I/O | Type | Function |
|---|--------|--------|--|
| CCLK0,1 | Input | LVCMOS | LVCMOS clock inputs |
| FSELA, FSELB, FSELC | Input | LVCMOS | Output bank divide select input |
| MR/ $\overline{\text{OE}}$ | Input | LVCMOS | Internal reset and output (high impedance) control |
| GND | | Supply | Negative voltage supply (GND) |
| V _{CCA} , V _{CCB} ⁽¹⁾ , V _{CCC} | | Supply | Positive voltage supply for output banks |
| V _{CC} | | Supply | Positive voltage supply for core (VCC) |
| QA0 – QA2 | Output | LVCMOS | Bank A outputs |
| QB0 – QB2 | Output | LVCMOS | Bank B outputs |
| QC0 – QC3 | Output | LVCMOS | Bank C outputs |

1. V_{CCB} is internally connected to V_{CC}.

Table 2. Supported Single and Dual Supply Configurations

| Supply Voltage Configuration | V _{CC} ⁽¹⁾ | V _{CCA} ⁽²⁾ | V _{CCB} ⁽³⁾ | V _{CCC} ⁽⁴⁾ | GND |
|------------------------------|--------------------------------|---------------------------------|---------------------------------|---------------------------------|-----|
| 3.3 V | 3.3 V | 3.3 V | 3.3 V | 3.3 V | 0 V |
| Mixed Voltage Supply | 3.3 V | 3.3 V or 2.5 V | 3.3 V | 3.3 V or 2.5 V | 0 V |
| 2.5 V | 2.5 V | 2.5 V | 2.5 V | 2.5 V | 0 V |

- V_{CC} is the positive power supply of the device core and input circuitry. V_{CC} voltage defines the input threshold and levels.
- V_{CCA} is the positive power supply of the bank A outputs. V_{CCA} voltage defines bank A output levels.
- V_{CCB} is the positive power supply of the bank B outputs. V_{CCB} voltage defines bank B output levels. V_{CCB} is internally connected to V_{CC}.
- V_{CCC} is the positive power supply of the bank C outputs. V_{CCC} voltage defines bank C output levels.

Table 3. Function Table (Controls)

| Control | Default | 0 | 1 |
|----------------------------|---------|---------------------------------------|--|
| CCLK_SEL | 0 | CCLK0 | CCLK1 |
| FSELA | 0 | f _{QA0:2} = f _{REF} | f _{QA0:2} = f _{REF} ÷ 2 |
| FSELB | 0 | f _{QB0:2} = f _{REF} | f _{QB0:2} = f _{REF} ÷ 2 |
| FSELC | 0 | f _{QC0:3} = f _{REF} | f _{QC0:3} = f _{REF} ÷ 2 |
| MR/ $\overline{\text{OE}}$ | 0 | Outputs enabled | Internal reset outputs disabled (tristate) |

Table 4. Absolute Maximum Ratings⁽¹⁾

| Symbol | Characteristics | Min | Max | Unit | Condition |
|------------------|---------------------|------|----------------------|------|-----------|
| V _{CC} | Supply Voltage | -0.3 | 3.6 | V | |
| V _{IN} | DC Input Voltage | -0.3 | V _{CC} +0.3 | V | |
| V _{OUT} | DC Output Voltage | -0.3 | V _{CC} +0.3 | V | |
| I _{IN} | DC Input Current | | ±20 | mA | |
| I _{OUT} | DC Output Current | | ±50 | mA | |
| T _S | Storage Temperature | -65 | 125 | °C | |

1. Absolute maximum continuous ratings are those maximum values beyond which damage to the device may occur. Exposure to these conditions or conditions beyond those indicated may adversely affect device reliability. Functional operation under absolute-maximum-rated conditions is not implied.

Table 5. General Specifications

| Symbol | Characteristics | Min | Typ | Max | Unit | Condition |
|----------|-----------------------------------|------|-----------------|-----|------|------------|

| DC_Q | Output Duty Cycle | ± 1 or ± 2 output | 45 | 50 | 55 | % $DC_{REF} = 50\%$ |

1. AC characteristics apply for parallel output termination of 50 Ω to V_{TT} .
2. For all other AC specifications, refer to 2.5 V or 3.3 V tables according to the supply voltage of the output bank.
3. Output pulse skew $t_{sk(P)}$ is the absolute difference of the propagation delay times: $|t_{PLH} - t_{PHL}|$. Output duty cycle is frequency dependent: $DC_Q = (0.5 \pm t_{sk(P)} \cdot f_{OUT})$.

APPLICATIONS INFORMATION

Driving Transmission Lines

The MPC9446 clock driver was designed to drive high-speed signals in a terminated transmission line environment. To provide the optimum flexibility to the user, the output drivers were designed to exhibit the lowest impedance possible. With an output impedance of less than $20\ \Omega$, the drivers can drive either parallel or series terminated transmission lines. For more information on transmission lines the reader is referred to Freescale application note AN1091. In most high performance clock networks, point-to-point distribution of signals is the method of choice. In a point-to-point scheme, either series terminated or parallel terminated transmission lines can be used. The parallel technique terminates the signal at the end of the line with a $50\ \Omega$ resistance to $V_{CC}/2$.

This technique draws a fairly high level of DC current, and thus, only a single terminated line can be driven by each output of the MPC9446 clock driver. For the series terminated case, however, there is no DC current draw; thus, the outputs can drive multiple series terminated lines. Figure 3 illustrates an output driving a single series terminated line versus two series terminated lines in parallel. When taken to its extreme, the fanout of the MPC9446 clock driver is effectively doubled due to its capability to drive multiple lines.

Figure 3. Single versus Dual Transmission Lines

The waveform plots in Figure 4 show the simulation results of an output driving a single line versus two lines. In both cases, the drive capability of the MPC9446 output buffer is more than sufficient to drive $50\ \Omega$ transmission lines on the incident edge. Note from the delay measurements in the simulations, a delta of only 43 ps exists between the two differently loaded outputs. This suggests that the dual line driving need not be used exclusively to maintain the tight output-to-output skew of the MPC9446. The output waveform in Figure 4 shows a step in the waveform. This step is caused by the impedance mismatch seen looking into the driver. The parallel combination of the $36\ \Omega$ series resistor plus the output impedance does not match the parallel combination of

the line impedances. The voltage wave launched down the two lines will equal:

$$V_L = V_S (Z_0 \div (R_S + R_0 + Z_0))$$

$$Z_0 = 50\ \Omega \parallel 50\ \Omega$$

$$R_S = 36\ \Omega \parallel 36\ \Omega$$

$$R_0 = 14\ \Omega$$

$$V_L = 3.0 (25 \div (18 + 14 + 25)) \\ = 1.31\ \text{V}$$

At the load end, the voltage will double, due to the near unity reflection coefficient, to 2.5 V. It will then increment towards the quiescent 3.0 V in steps separated by one round trip delay (in this case 4.0 ns).

Figure 4. Single versus Dual Waveforms

Since this step is well above the threshold region, it will not cause any false clock triggering; however, designers may be uncomfortable with unwanted reflections on the line. To better match the impedances when driving multiple lines, the situation in Figure 5 should be used. In this case, the series terminating resistors are reduced such that when the parallel combination is added to the output buffer impedance, the line impedance is perfectly matched.

Figure 5. Optimized Dual Line Termination
