

## 2.5V LVDS, 1:2 CLOCK BUFFER TERABUFFER™ II

**IDT5T9302**

### General Description

The IDT5T9302 2.5V differential clock buffer is a user-selectable differential input to two LVDS outputs. The fanout from a differential input to two LVDS outputs reduces loading on the preceding driver and provides an efficient clock distribution network. The IDT5T9302 can act as a translator from a differential HSTL, eHSTL, LVEPECL (2.5V), LVPECL (3.3V), CML, or LVDS input to LVDS outputs. A single-ended 3.3V / 2.5V LVTTTL input can also be used to translate to LVDS outputs. The redundant input capability allows for an asynchronous change-over from a primary clock source to a secondary clock source. Selectable reference inputs are controlled by SEL.

The IDT5T9302 outputs can be asynchronously enabled/disabled. When disabled, the outputs will drive to the value selected by the GL pin. Multiple power and grounds reduce noise.

### Features

- Guaranteed low skew: 5ps (typical)
- Very low duty cycle distortion: 20ps (typical)
- High speed propagation delay: 1.35ns (typical)
- Up to 450MHz operation
- Selectable inputs
- Hot insertable and over-voltage tolerant inputs
- 3.3V/2.5V LVTTTL, HSTL eHSTL, LVEPECL (2.5V), LVPECL (3.3V), CML or LVDS input interface
- Selectable differential inputs to two LVDS outputs
- Power-down mode
- 2.5V V<sub>DD</sub>
- -40°C to 85°C ambient operating temperature
- Available in TSSOP package

### Block Diagram

**Table 1. Pin Descriptions**

Name	Type		Description
A[1:2]	Input	Adjustable <sup>(1, 4)</sup>	Clock input. A[1:2] is the "true" side of the differential clock input.
$\overline{A[1:2]}$	Input	Adjustable <sup>(1, 4)</sup>	Complementary clock inputs. $\overline{A[1:2]}$ is the complementary side of A[1:2]. For LVTTTL single-ended operation, $\overline{A[1:2]}$ should be set to the desired toggle voltage for A[1:2]: 3.3V LVTTTL VREF = 1650mV 2.5V LVTTTL VREF = 1250mV
$\overline{G}$	Input	LVTTTL	Gate control for differential outputs Q1, $\overline{Q1}$ and Q2, $\overline{Q2}$ . When $\overline{G}$ is LOW, the differential outputs are active. When $\overline{G}$ is HIGH, the differential outputs are asynchronously driven to the level designated by GL <sup>(2)</sup> . See Table 3A.
GL	Input	LVTTTL	Specifies output disable level. If HIGH, "true" outputs disable HIGH and "complementary" outputs disable LOW. If LOW, "true" outputs disable LOW and "complementary" outputs disable HIGH. See Table 3A.
Q[1:2]	Output	LVDS	Clock outputs.
$\overline{Q[1:2]}$	Output	LVDS	Complementary clock outputs.
SEL	Input	LVTTTL	Reference clock select. When LOW, selects A2 and $\overline{A2}$ . When HIGH, selects A1 and $\overline{A1}$ . See Table 3B.
$\overline{PD}$	Input	LVTTTL	Power-down control. Shuts off entire chip. If LOW, the device goes into low power mode. Inputs and outputs are disabled. Both "true" and "complementary" outputs will pull to VDD. Set HIGH for normal operation. <sup>(3)</sup>
V <sub>DD</sub>		Power	Power supply for the device core and inputs.
GND		Power	Power supply return for all power.
nc			No connect; recommended to connect to GND.

## NOTES:

- Inputs are capable of translating the following interface standards:  
Single-ended 3.3V and 2.5V LVTTTL levels  
Differential HSTL and eHSTL levels  
Differential LVEPECL (2.5V) and LVPECL (3.3V) levels  
Differential LVDS levels  
Differential CML levels
- Because the gate controls are asynchronous, runt pulses are possible. It is the user's responsibility to either time the gate control signals to minimize the possibility of runt pulses or be able to tolerate them in down stream circuitry.
- It is recommended that the outputs be disabled before entering power-down mode. It is also recommended that the outputs remain disabled until the device completes power-up after asserting PD.
- The user must take precautions with any differential input interface standard being used in order to prevent instability when there is no input signal.

## Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics* or *AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

Item	Rating
Power Supply Voltage, $V_{DD}$	-0.5V to +3.6V
Input Voltage, $V_I$	-0.5V to +3.6V
Output Voltage, $V_O$ Not to exceed 3.6V	-0.5 to $V_{DD} + 0.5V$
Storage Temperature, $T_{STG}$	-65°C to 150°C
Junction Temperature, $T_J$	150°C

$t_{PWRUP}$	Output Gate Disable Crossing $V_{THI}$ to $Q_n/\overline{Q_n}$ Driven to Designated Level				100	$\mu\text{S}$

NOTE 1. AC propagation measurements should not be taken within the first 100 cycles of startup.

NOTE 2. Skew measured between crosspoints of all differential output pairs under identical input and output interfaces, transitions and load conditions on any one device.

NOTE 3. Skew measured is the difference between propagation delay times  $t_{pHL}$  and  $t_{pLH}$  of any differential output pair under identical input and output interfaces, transitions and load conditions on any one device.

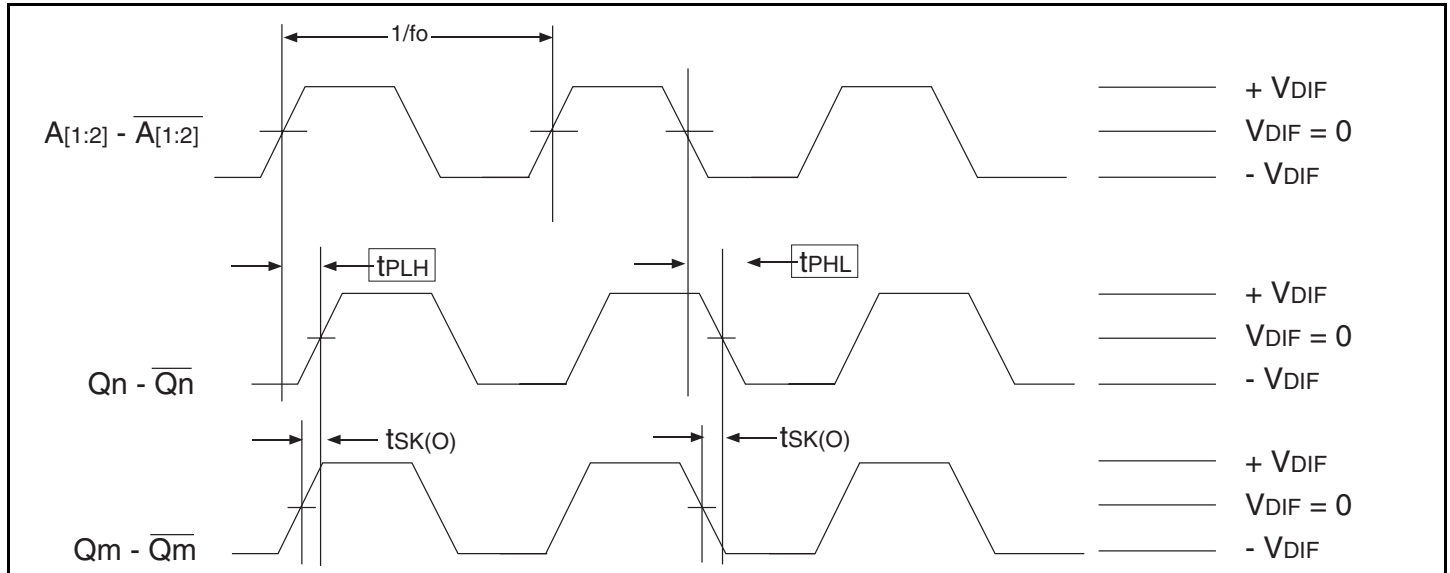

NOTE 4. Skew measured is the magnitude of the difference in propagation times between any single differential output pair of two devices, given identical transitions and load conditions at identical VDD levels and temperature.

NOTE 5. All parameters are tested with a 50% input duty cycle.

NOTE 6. Guaranteed by design but not production tested.

## Differential AC Timing Waveforms

### Output Propagation and Skew Waveforms

NOTE 1: Pulse skew is calculated using the following expression:

$$t_{sk}(p) = |t_{pHL} - t_{pLH}|$$

Note that the  $t_{pHL}$  and  $t_{pLH}$  shown above are not valid measurements for this calculation because they are not taken from the same pulse.

NOTE 2: AC propagation measurements should not be taken within the first 100 cycles of startup.

### Differential Gate Disabled/Enable Showing Runt Pulse Generation

NOTE 1: As shown, it is possible to generate runt pulses on gate disable and enable of the outputs. It is the user's responsibility to time the  $\overline{G}$  signal to avoid this problem.

## Power Down Timing

NOTE 1: It is recommended that outputs be disabled before entering power-down mode. It is also recommended that the outputs remain disabled until the device completes power-up after asserting PD.

NOTE 2: The *Power Down Timing* diagram assumes that GL is HIGH.

NOTE 3: It should be noted that during power-down mode, the outputs are both pulled to  $V_{DD}$ . In the *Power Down Timing* diagram this is shown when Qn/ $\overline{Qn}$  goes to  $V_{DIF} = 0$ .

$R_L$	50	$\Omega$

NOTE 1: Specifications only apply to “Normal Operations” test condition. The  $T_{IA}/E_{IA}$  specification load is for reference only.

NOTE 2: The scope inputs are assumed to have a 2pF load to ground.  $T_{IA}/E_{IA} - 644$  specifies 5pF between the output pair. With  $C_L = 8pF$ , this gives the test circuit appropriate 5pF equivalent load.
