

# Smart Highside High Current Power Switch

## Reversave™

- Reverse battery protection by self turn on of power MOSFET

## Features

- Overload protection
- Current limitation
- Short circuit protection
- Overtemperature protection
- Overvoltage protection (including load dump)
- Clamp of negative voltage at output
- Fast deenergizing of inductive loads <sup>1)</sup>
- Low ohmic inverse current operation
- Diagnostic feedback with load current sense
- Open load detection via current sense
- Loss of  $V_{bb}$  protection<sup>2)</sup>
- **Electrostatic discharge (ESD)** protection

## Application

- Power switch with current sense diagnostic feedback for 12V and 24V DC grounded loads
- Most suitable for loads with high inrush current like lamps and motors; all types of resistive and inductive loads
- Replaces electromechanical relays, fuses and discrete circuits

## Product Summary

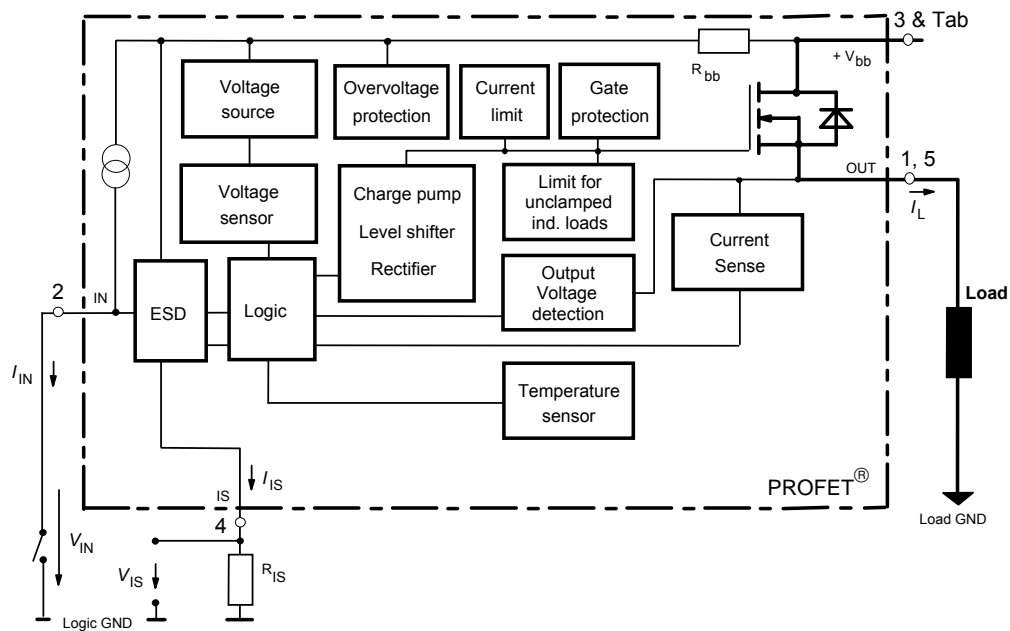

|                                  |                |            |    |
|----------------------------------|----------------|------------|----|
| Overvoltage protection           | $V_{bb(AZ)}$   | 62         | V  |
| Output clamp                     | $V_{ON(CL)}$   | 44         | V  |
| Operating voltage                | $V_{bb(on)}$   | 5.0 ... 34 | V  |
| On-state resistance              | $R_{ON}$       | 3.6        | mΩ |
| Load current (ISO)               | $I_{L(ISO)}$   | 115        | A  |
| Short circuit current limitation | $I_{L(SC)}$    | 220        | A  |
| Current sense ratio              | $I_L : I_{IS}$ | 21000      |    |

TO-218AB/5

## General Description

N channel vertical power FET with charge pump, current controlled input and diagnostic feedback with load current sense, integrated in Smart SiPMOS® chip on chip technology. Providing embedded protective functions.

1) With additional external diode.

2) Additional external diode required for energized inductive loads (see page 9).

| Pin | Symbol            | Function   |
|-----|-------------------|--|
| 1   | OUT O             | Output to the load. The pins 1 and 5 must be shorted with each other especially in high current applications! <sup>3)</sup>  |
| 2   | IN I              | Input, activates the power switch in case of short to ground   |
| 3   | V <sub>bb</sub> + | Positive power supply voltage, the tab is electrically connected to this pin. In high current applications the tab should be used for the V <sub>bb</sub> connection instead of this pin <sup>4)</sup> . |
| 4   | IS S              | Diagnostic feedback providing a sense current proportional to the load current; zero current on failure (see Truth Table on page 7)  |
| 5   | OUT O             | Output to the load. The pins 1 and 5 must be shorted with each other especially in high current applications! <sup>3)</sup>  |

**Maximum Ratings** at  $T_j = 25\text{ °C}$  unless otherwise specified

| Parameter  | Symbol                               | Values       | Unit |
|--|--------------------------------------|--------------|------|
| Supply voltage (overvoltage protection see page 4)   | V <sub>bb</sub>                      | 40           | V    |

| Power dissipation (DC), $T_C \leq 25\text{ °C}$  | $P_{tot}$                            | 360          | W    |
| Inductive load switch-off energy dissipation, single pulse<br>$V_{bb} = 12\text{ V}$ , $T_{j,start} = 150\text{ °C}$ , $T_C = 150\text{ °C}$ const.,<br>$I_L = 20\text{ A}$ , $Z_L = 15\text{ mH}$ , $0\ \Omega$ , see diagrams on page 10 | $E_{AS}$                             | 3            | J    |
| Electrostatic discharge capability (ESD)<br>Human Body Model acc. MIL-STD883D, method 3015.7 and ESD<br>assn. std. S5.1-1993, C = 100 pF, R = 1.5 k $\Omega$   | V <sub>ESD</sub>                     | 4            | kV   |
| Current through input pin (DC)   | $I_{IN}$                             | +15, -250    | mA   |
| Current through current sense status pin (DC)<br>see internal circuit diagrams on page 8   | $I_{IS}$                             | +15, -250    |      |

- 3) Not shorting all outputs will considerably increase the on-state resistance, reduce the peak current capability and decrease the current sense accuracy
- 4) Otherwise add up to 0.5 m $\Omega$  (depending on used length of the pin) to the R<sub>ON</sub> if the pin is used instead of the tab.
- 5) R<sub>i</sub> = internal resistance of the load dump test pulse generator.
- 6) V<sub>Load dump</sub> is setup without the DUT connected to the generator per ISO 7637-1 and DIN 40839.

**Thermal Characteristics**

7) Thermal resistance  $R_{thCH}$  case to heatsink (about 0.25 K/W with silicone paste) not included!

8) Decrease of  $V_{bb}$  below 10 V causes a slowly a dynamic increase of  $R_{ON}$  to a higher value of  $R_{ON(Static)}$ . As long as  $V_{BIN} > V_{BIN(u)max}$ ,  $R_{ON}$  increase is less than 10 % per second for  $T_J < 85^\circ\text{C}$ .

9) not subject to production test, specified by design

10)  $T_J$  is about  $105^\circ\text{C}$  under these conditions.

11) See timing diagram on page 13.

<sup>12)</sup> If the device is turned on before a  $V_{bb}$ -decrease, the operating voltage range is extended down to  $V_{bIN(u)}$ . For the voltage range 0..34 V the device is fully protected against overtemperature and short circuit.

<sup>13)</sup>  $V_{bIN} = V_{bb} - V_{IN}$  see diagram on page 8. When  $V_{bIN}$  increases from less than  $V_{bIN(u)}$  up to  $V_{bIN(ucp)} = 5\text{ V}$  (typ.) the charge pump is not active and  $V_{OUT} \approx V_{bb} - 3\text{ V}$ .

<sup>14)</sup> See also  $V_{ON(CL)}$  in circuit diagram on page 9.

<sup>15)</sup> Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as "outside" normal operating range. Protection functions are not designed for continuous repetitive operation.

<sup>16)</sup> Short circuit is a failure mode. The device is not designed to operate continuously into a short circuit by permanent resetting the short circuit latch function. The lifetime will be reduced under such conditions.

<sup>17)</sup> This output clamp can be "switched off" by using an additional diode at the IS-Pin (see page 8). If the diode is used,  $V_{OUT}$  is clamped to  $V_{bb} - V_{ON(CL)}$  at inductive load switch off.

<sup>18)</sup> The reverse load current through the intrinsic drain-source diode has to be limited by the connected load (as it is done with all polarity symmetric loads). Note that under off-conditions ( $I_{IN} = I_{IS} = 0$ ) the power transistor is not activated. This results in raised power dissipation due to the higher voltage drop across the intrinsic drain-source diode. The temperature protection is not active during reverse current operation! Increasing reverse battery voltage capability is simply possible as described on page 9.

Overtemperature reset by cooling:  $T_j < T_{jt}$  (see diagram on page 14)

Short circuit to GND: Shutdown remains latched until next reset via input (see diagram on page 13)

- 22) Low ohmic short to  $V_{bb}$  may reduce the output current  $I_L$  and can thus be detected via the sense current  $I_{IS}$ .
- 23) Power Transistor "OFF", potential defined by external impedance.
- 24) Latch except when  $V_{bb} - V_{OUT} < V_{ON(SC)}$  after shutdown. In most cases  $V_{OUT} = 0\text{ V}$  after shutdown ( $V_{OUT} \neq 0\text{ V}$  only if forced externally). So the device remains latched unless  $V_{bb} < V_{ON(SC)}$  (see page 5). No latch between turn on and  $t_{d(SC)}$ .
- 25) Can be "switched off" by using a diode  $D_S$  (see page 8) or leaving open the current sense output.

**Terms**

Two or more devices can easily be connected in parallel to increase load current capability.

**RON measurement layout**

**Input circuit (ESD protection)**

When the device is switched off ( $I_{IN} = 0$ ) the voltage between IN and GND reaches almost  $V_{bb}$ . Use a mechanical switch, a bipolar or MOS transistor with appropriate breakdown voltage as driver.  $V_{Z,IN} = 64\text{ V}$  (typ.).

**Current sense status output**

$V_{Z,IS} = 64\text{ V}$  (typ.),  $R_{IS} = 1\text{ k}\Omega$  nominal (or  $1\text{ k}\Omega/n$ , if  $n$  devices are connected in parallel).  $I_S = I_L/K_{IIS}$  can be driven only by the internal circuit as long as  $V_{OUT} - V_{IS} > 5\text{ V}$ . If you want to measure load currents up to  $I_{L(M)}$ ,  $R_{IS}$  should be less than  $\frac{V_{bb} - 5\text{ V}}{I_{L(M)} / K_{IIS}}$ .

Note: For large values of  $R_{IS}$  the voltage  $V_{IS}$  can reach almost  $V_{bb}$ . See also overvoltage protection. If you don't use the current sense output in your application, you can leave it open.

**Short circuit detection**

Fault Condition:  $V_{ON} > V_{ON(SC)}$  (6 V typ.) and  $t > t_{d(SC)}$  (80 ...350  $\mu\text{s}$ ).

**Inductive and overvoltage output clamp**

$V_{ON}$  is clamped to  $V_{ON(CI)} = 42\text{ V}$  typ. At inductive load switch-off without  $D_S$ ,  $V_{OUT}$  is clamped to

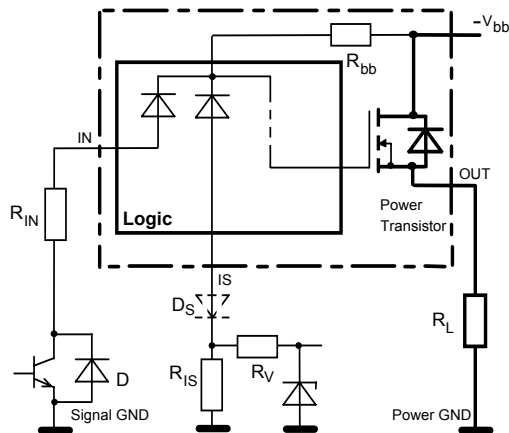

$V_{OUT(CL)} = -19V$  typ. via  $V_{ZG}$ . With  $D_S$ ,  $V_{OUT}$  is clamped to  $V_{bb} - V_{ON(CL)}$  via  $V_{Z1}$ . Using  $D_S$  gives faster deenergizing of the inductive load, but higher peak power dissipation in the PROFET. In case of a floating ground with a potential higher than 19V referring to the OUT – potential the device will switch on, if diode  $D_S$  is not used.

**Overvoltage protection of logic part**

$R_{bb} = 120\Omega$  typ.,  $V_{Z,IN} = V_{Z,IS} = 64V$  typ.,  $R_{IS} = 1k\Omega$  nominal. Note that when overvoltage exceeds 69V typ. a voltage above 5V can occur between IS and GND, if  $R_V$ ,  $V_{Z,VIS}$  are not used.

**Reverse battery protection**

$R_V \geq 1k\Omega$ ,  $R_{IS} = 1k\Omega$  nominal. Add  $R_{IN}$  for reverse battery protection in applications with  $V_{bb}$  above 16V<sup>18</sup>); recommended value:  $\frac{1}{R_{IN}} + \frac{1}{R_{IS}} + \frac{1}{R_V} = \frac{0.1A}{|V_{bb}| - 12V}$  if  $D_S$  is not used (or  $\frac{1}{R_{IN}} = \frac{0.1A}{|V_{bb}| - 12V}$  if  $D_S$  is used).

To minimize power dissipation at reverse battery operation, the summarized current into the IN and IS pin should be about 120mA. The current can be provided by using a small signal diode D in parallel to the input switch, by using a MOSFET input switch or by proper adjusting the current through  $R_{IS}$  and  $R_V$ .

**V<sub>bb</sub> disconnect with energized inductive load**

Provide a current path with load current capability by using a diode, a Z-diode, or a varistor. ( $V_{ZL} < 72V$  or  $V_{Zb} < 30V$  if  $R_{IN}=0$ ). For higher clamp voltages currents at IN and IS have to be limited to 250 mA.

Version a:

Version b:

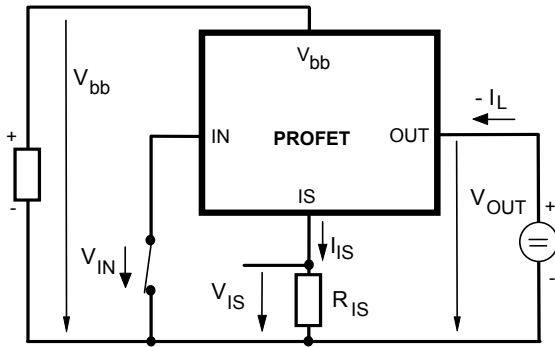

Note that there is no reverse battery protection when using a diode without additional Z-diode  $V_{ZL}$ ,  $V_{Zb}$ .

Version c: Sometimes a necessary voltage clamp is given by non inductive loads  $R_L$  connected to the same switch and eliminates the need of clamping circuit:

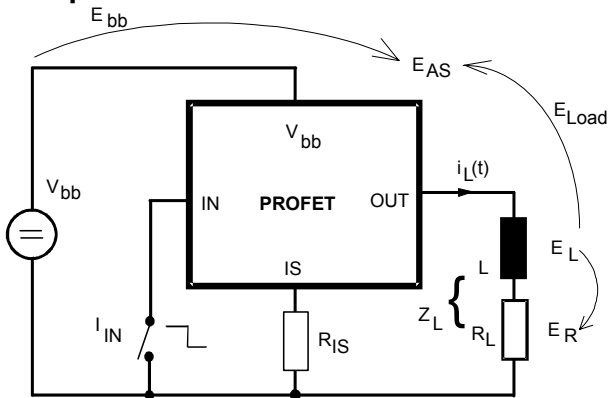

**Inverse load current operation**

The device is specified for inverse load current operation ( $V_{OUT} > V_{bb} > 0V$ ). The current sense feature is not available during this kind of operation ( $I_{IS} = 0$ ). With  $I_{IN} = 0$  (e.g. input open) only the intrinsic drain source diode is conducting resulting in considerably increased power dissipation. If the device is switched on ( $V_{IN} = 0$ ), this power dissipation is decreased to the much lower value  $R_{ON(INV)} \cdot I^2$  (specifications see page 4).  
 Note: Temperature protection during inverse load current operation is not possible!

**Inductive load switch-off energy dissipation**

Energy stored in load inductance:

$$E_L = \frac{1}{2} \cdot L \cdot I_L^2$$

While demagnetizing load inductance, the energy dissipated in PROFET is

$$E_{AS} = E_{bb} + E_L - E_R = V_{ON(CL)} \cdot i_L(t) dt,$$

with an approximate solution for  $R_L > 0 \Omega$ :

$$E_{AS} = \frac{I_L \cdot L}{2 \cdot R_L} (V_{bb} + |V_{OUT(CL)}|) \ln \left( 1 + \frac{I_L \cdot R_L}{|V_{OUT(CL)}|} \right)$$

**Maximum allowable load inductance for a single switch off**

$$L = f(I_L); T_{j,start} = 150^\circ C, V_{bb} = 12V, R_L = 0 \Omega$$

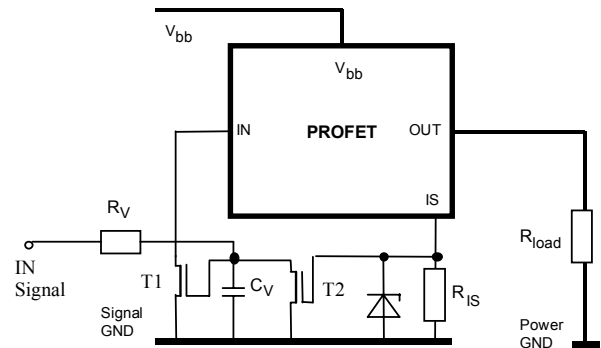

L [ $\mu H$ ]

$I_L$  [A]

**Externally adjustable current limit**

If the device is conducting, the sense current can be used to reduce the short circuit current and allow higher lead inductance (see diagram above). The device will be turned off, if the threshold voltage of T2 is reached by  $I_s \cdot R_{IS}$ . After a delay time defined by  $R_V \cdot C_V$  T1 will be reset. The device is turned on again, the short circuit current is defined by  $I_{L(SC)}$  and the device is shut down after  $t_{d(SC)}$  with latch function.

## Characteristics

### Current sense versus load current:

$$I_{IS} = f(I_L)$$

$I_{IS}$  [mA]

$I_L$  [A]

### Current sense ratio:

$$K_{ILIS} = f(I_L), T_J = 25\text{ °C}$$

$K_{ILIS}$

$I_L$  [A]

### Current sense ratio:

$$K_{ILIS} = f(I_L), T_J = -40\text{ °C}$$

$K_{ILIS}$

$I_L$  [A]

### Current sense ratio:

$$K_{ILIS} = f(I_L), T_J = 150\text{ °C}$$

$K_{ILIS}$

$I_L$  [A]

**Typ. current limitation characteristic**  
 $I_L = f(V_{ON}, T_j)$

$I_L$  [A]

$V_{ON}$  [V]

In case of  $V_{ON} > V_{ON(SC)}$  (typ. 6 V) the device will be switched off by internal short circuit detection.

**Typ. on-state resistance**  
 $R_{ON} = f(V_{bb}, T_j); I_L = 20\text{ A}; V_{IN} = 0$

$R_{ON}$  [mOhm]

$V_{bb}$  [V]

**Typ. input current**

$I_{IN} = f(V_{bIN}), V_{bIN} = V_{bb} - V_{IN}$

$I_{IN}$  [mA]

$V_{bIN}$  [V]

## Timing diagrams

**Figure 1a:** Switching a resistive load, change of load current in on-condition:

The sense signal is not valid during a settling time after turn-on/off and after change of load current.

**Figure 2a:** Switching motors and lamps:

Sense current saturation can occur at very high inrush currents (see  $I_{IS,lim}$  on page 6).

**Figure 2b:** Switching an inductive load:

**Figure 3a:** Short circuit:

shut down by short circuit detection, reset by  $I_{IN} = 0$ .

Shut down remains latched until next reset via input.
