

# Intel® IXP1240 Network Processor

Datasheet

## Product Features

The Intel® IXP1240 Network Processor delivers high-performance processing power and flexibility to a wide variety of LAN and telecommunications products. Distinguishing features of the IXP1240 are the performance of ASIC hardware along with programmability of a microprocessor.

- **Applications**
  - Multi-layer LAN Switches
  - Multi-protocol Telecommunications Products
  - Broadband Cable Products
  - Remote Access Devices
  - Intelligent PCI adapters
- **Integrated StrongARM Core**
  - High-performance, low-power, 32-bit Embedded RISC processor
  - 16 Kbyte instruction cache
  - 8 Kbyte data cache
  - 512 byte mini-cache for data that is used once and then discarded
  - Write buffer
  - Memory management unit
  - Access to IXP1240 FBI Unit, PCI Unit and SDRAM Unit via the ARM\* AMBA Bus
- **Six Integrated Programmable Microengines**
  - Operating frequency of up to 232 MHz
  - Multi-thread support of four threads per microengine
  - Single-cycle ALU and shift operations
  - Zero context swap overhead
  - Large Register Set: 128 General-Purpose and 128 Transfer Registers
  - 2 K x 32-bit Instruction Control Store
  - Access to the IXP1240 FBI Unit, PCI DMA channels, SRAM, and SDRAM
- **High Bandwidth I/O Bus (IX Bus)**
  - 64-bit, up to 104 MHz operation
  - 6.6 Gbps peak bandwidth
  - 64-bit or dual 32-bit bus options
- **Integrated 32-bit, 66 MHz PCI Interface**
  - Supports *PCI Local Bus Specification Revision 2.2* as a Bus Master
  - 264 Mbytes/sec peak burst mode operation
  - I<sub>2</sub>O\* support for StrongARM Core
  - Dual DMA channels
- **Industry Standard 64-bit SDRAM Interface**
  - Peak bandwidth of up to 928 Mbytes/sec
  - Address up to 256 Mbytes of SDRAM
  - Memory bandwidth improvement through bank switching
  - Read-modify-write support
  - Byte aligner/merger
  - Cyclic Redundancy Check (CRC)
- **Industry Standard 32-bit SRAM Interface**
  - Peak bandwidth of up to 464 Mbytes/sec
  - Address up to 8 Mbytes of SRAM
  - Up to 8 Mbytes FlashROM for booting StrongARM Core
  - Supports atomic push/pop operations
  - Supports atomic bit set and bit clear operations
  - Memory bandwidth improvement by reduced read/write turnaround bus cycles
- **Other Integrated Features**
  - Hardware Hash Unit for generation of 48- or 64-bit adaptive polynomial hash keys
  - Serial UART port
  - Real Time Clock
  - Four general-purpose I/O pins
  - Four 24-bit timers with CPU watchdog support
  - Limited JTAG Support
  - 4 Kbyte Scratchpad Memory
- **432-pin, HL-PBGA package**
- **2 V CMOS device**
  - 3.3 V tolerant I/O

**Notice:** This document contains preliminary information on new products in production. The specifications are subject to change without notice. Verify with your local Intel sales office that you have the latest datasheet before finalizing a design.

Part Number: 278405-003  
December 2001

## Revision History

## 1.0 Product Description

The Intel® IXP1240 Network Processor is a highly integrated, hybrid data processor that delivers high-performance parallel processing power and flexibility to a wide variety of networking, communications, and other data-intensive products. The IXP1240 is designed specifically as a data control element for applications that require access to a fast memory subsystem, a fast interface to I/O devices such as network MAC devices, and processing power to perform efficient manipulation on bits, bytes, words, and longword data.

The IXP1240 combines the popular StrongARM® processor with six independent 32-bit RISC data engines with hardware multithread support that combined, provide over 1 giga-operations per second. The Microengines contain the processing power to perform tasks typically reserved for high speed ASICs. In LAN switching applications, the six Microengines are capable of packet forwarding of over 3 million Ethernet packets per second at Layer 3. The StrongARM® processor can then be used for more complex tasks such as address learning, building and maintaining forwarding tables, and network management.

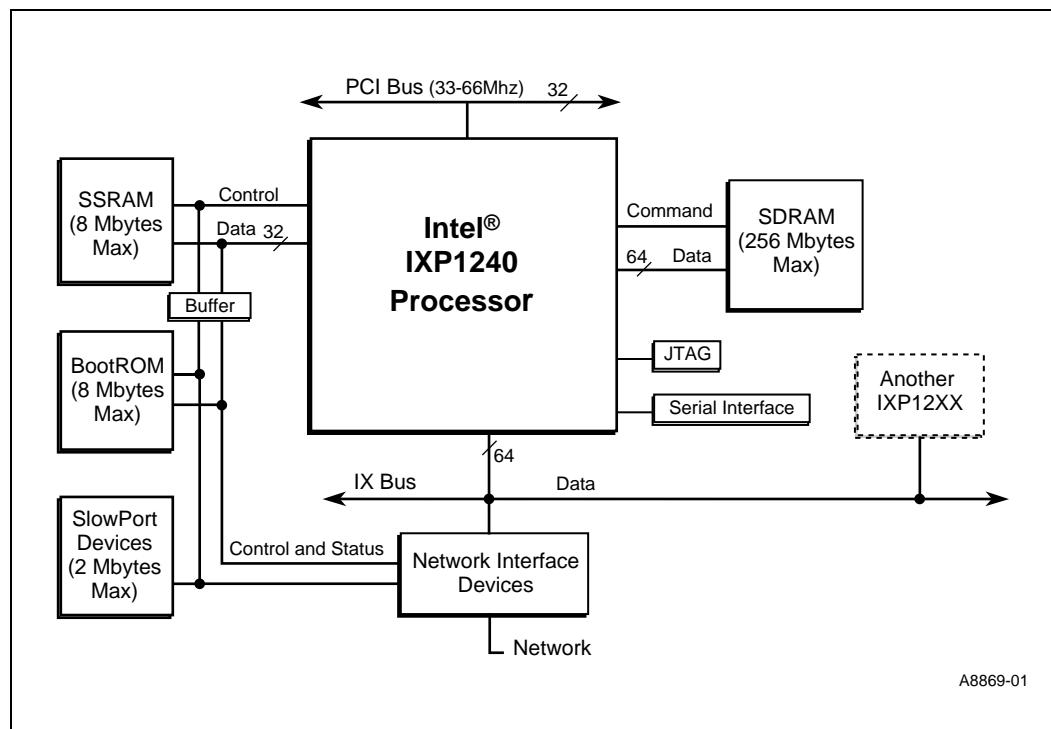

**Figure 1. Block Diagram**

As shown in [Figure 2](#):

- The IXP1240 interfaces to a maximum of 256 Mbytes of SDRAM over a 64-bit data bus.
- A separate 32-bit SRAM bus supports up to 8 Mbytes of SSRAM and 8 Mbytes of BootROM. The SRAM Bus also supports memory-mapped I/O devices within a 2 Mbyte memory space.
- A 32-bit PCI interface supports interfacing with industry-standard PCI devices.
- The IX Bus, a flexible 64-bit or dual 32-bit interface, supports attachment of MACs, framers, custom logic devices, and an additional network processor (IXP1200, IXP1240, or IXP1250).
- An asynchronous serial interface is supported for a debugger console over an RS-232 link.
- An IEEE 1149.1 interface is supported for Boundary Scan testing.

[Figure 2. System Block Diagram](#)

## 2.0 Functional Units

---

### 2.1 Conventions

- In all signal descriptions, an active low signal is indicated by the \_L in the signal name.
- In this and related IXP1240 documents, a word is equal to 16 bits, a longword is equal to 32 bits, and a quadword is equal to 64 bits. StrongARM® processor documents and the ARM® V4.0 Architecture Reference typically refer to a word as being equal to 32 bits, and a halfword as being equal to 16 bits.

### 2.2 StrongARM® Core

The StrongARM® core is the same industry standard 32-bit RISC processor as used in the Intel® StrongARM® SA-1100. It is compatible with the StrongARM® processor family currently used in applications such as network computers, PDAs, palmtop computers and portable telephones. The differentiating feature of the StrongARM® processor is that it provides very high performance in a low-power, compact design. This makes it feasible to combine it with a collection of other dedicated execution units on the same silicon die.

The StrongARM® core processor and six RISC Microengines provide the processing power required to forward greater than 3 million Ethernet packets per second through the IXP1240. A multi-IXP1200 Network Processor Family system scales linearly so that a system comprised of eight IXP1200s can process over 24 million packets per second.

The designer can partition his/her application by allocating Microengines, threads, and StrongARM® tasks. If necessary, multiple IXP1200 Network Processor Family devices can be used to aggregate CPU MIPs, increase data bandwidth, increase port fanout and density, or some combination of all three metrics.

The StrongARM® core operates at a frequency determined by programming the Phase-Locked Loop Configuration register (PLL\_CFG) and the maximum rated operating frequency of the IXP1240 device selected. The IXP1240 is currently available with an  $F_{core}$  operating frequency of 166, 200, or 232 MHz.

### 2.3 Microengines

Six 32-bit, multithreaded RISC Microengines perform data movement and processing without assistance from the StrongARM® core. Each Microengine has four independent program counters, zero overhead context switching and hardware semaphores from other hardware units to ensure that each Microengine can be fully utilized. A Microengine's powerful ALU and shifter perform both ALU and shift operations in a single cycle. The instruction set was specifically designed for networking and communications applications that require bit, byte, word and longword operations to forward data quickly and efficiently. Each Microengine contains a large amount of local memory and registers: 8 Kbytes organized as 2048 by 32 bits of high-speed RAM Control Store for program execution, 128 32-bit General Purpose Registers, and 128 32-bit transfer registers to service the SRAM and SDRAM Units.

The Microengines operate at the core clock frequency ( $F_{core}$ ).

## 2.4 FBI Unit and the IX Bus

The FBI Unit is responsible for servicing fast peripherals, such as MAC-layer devices, on the IX Bus. This includes moving data to and from the IXP1240 Receive and Transmit FIFOs.

The IX Bus provides a 4.4 Gbps interface to peripheral devices. The IX Bus was specifically designed to provide a simple and efficient interface. The IX Bus can be configured as either a 64-bit bidirectional bus or as two 32-bit unidirectional buses. The maximum operating frequency of the IX Bus is 104 MHz.

Two IXP1200 Network Processor Family devices can be placed on a single IX Bus in shared IX Bus mode. This option is supported only in 64-bit bidirectional mode.

The FBI Unit contains the Transmit and Receive FIFO elements, control and status registers (CSRs), a 4 Kbyte Scratchpad RAM, and a Hash Unit for generating 48- and 64-bit hash keys. It also contains the drivers and receivers for the IX Bus.

The IX Bus consists of 64 data pins, 23 control pins, and a clock input pin. A sideband bus operating in parallel to the IX Bus, called the Ready Bus, consists of eight additional data pins and five control pins.

The Ready Bus is synchronous to the IX Bus clock, but operation is controlled by a programmable hardware sequencer. Ready Bus cycles are separate and distinct from IX Bus cycles. Up to twelve sequencer commands are loaded at chip initialization time, and run in a continuous loop. The commands can consist of sampling FIFO status for the IX Bus devices, sending Flow Control messages to MAC devices, and reads/writes to other IXP1200 Network Processor Family devices as required by the application design. Refer to the *IXP1200 Network Processor Family Hardware Reference Manual* for specific details on using the Ready Bus.

### 2.4.1 IX Bus Access Behavior

There are two basic modes of IX Bus operation. This is a configuration option only and is not intended to be used “on the fly” to switch between modes.

- 64-Bit Bidirectional Mode

The entire 64-bit data path FDAT[63:0] is used for reads or writes to IX Bus devices. The IXP1240 always drives and receives all 64 bits of the IX Bus in this mode. Valid bytes are indicated on the FBE\_L[7:0] signals driven by the IXP1240 during writes and by the IX Bus slave device on reads.

- 32-Bit Unidirectional Mode

The IX Bus is split into independent 32-bit transmit and 32-bit receive data paths. Transmit data is driven on FDAT[63:32] and receive data is input on FDAT[31:0]. In this mode, the transmit path is always driven. The receive path is an input during receive cycles and driven by the IXP1240 during device reset cycles or during prolonged idle time on the bus. Valid bytes are identified for the transmit path by the FBE\_L[7:4] signals. Valid bytes are identified for the receive path by the FBE\_L[3:0] signals.

Each basic mode has two additional modes depending on the number of IX Bus devices and ports being used: 1-2 MAC mode for one or two slave devices, and 3+ MAC mode when using three to seven slave devices. Bus timing and the functions of the IX Bus signals are slightly different in each mode. These functional definitions per IX Bus mode are listed in [Section 3.6](#) and [Section 3.7](#).

In addition, a shared IX Bus mode is supported in 64-bit bidirectional mode. Refer to the list at the bottom of [Table 26](#) for the signals that the IX Bus masters must drive and IX Bus slaves must tri-state.

The IX Bus and Intel devices using the IX Bus, such as the 21440 and IXF1002, observe a pipelined bus protocol. When receive transfers are terminated early, the pipeline continues to cause several extra bus cycles depending on when the EOP signal was asserted. Data is a “don’t care” for these trailing bus cycles, except in the case of a status transfer where the IX Bus burst includes a possible status transfer if the device were programmed to support it. Slave devices must drive valid logic levels on the FDAT data pins during these cycles.

The tables below show the number of total IX Bus data cycles that will occur for a burst with EOP asserted at specific clocks for 64-bit and 32-bit IX Bus modes. In each case, the tables show IX Bus cycles with and without the optional status transfer cycle. Refer to the IX Bus Protocol Timing diagrams ([Figure 21](#) through [Figure 54](#)) when interpreting these tables.

**Table 1. 64-bit IX Bus Receive Remainder Cycles, No Status Transfer**

EOP signaled on this cycle:	1	2	3	4	5	6	7	8
# of bus cycles in burst:	5	6	7	8	8	8	8	8
# of Don't Care cycles:	4	4	4	4	3	2	1	0

**Table 2. 64-bit IX Bus Receive Remainder Cycles, with Status Transfer**

EOP signaled on this cycle:	1	2	3	4	5	6	7	8
# of bus cycles in burst:	5	6	7	8	8	8	8	8
Status transfer	1	1	1	1	1	1	1	Note 1
# of Don't Care cycles:	3	3	3	3	2	1	0	0

**NOTE:**

1. Status transfer occurs on a subsequent IX Bus status cycle.

**Table 3. 32-bit IX Bus Receive Remainder Cycles, No Status Transfer**

EOP signaled on this cycle:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
# of bus cycles in burst:	5	6	7	8	9	10	11	12	13	14	15	16	16	16	16	16
# of Don't Care cycles:	4	4	4	4	4	4	4	4	4	4	4	4	3	2	1	0

**Table 4. 32-bit IX Bus Receive Remainder Cycles, with Status Transfer**

EOP signaled on this cycle:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
# of bus cycles in burst:	5	6	7	8	9	10	11	12	13	14	15	16	16	16	16	16

**Table 4. 32-bit IX Bus Receive Remainder Cycles, with Status Transfer**

Status transfer	32-bit status	1	1	1	1	1	1	1	1	1	1	1	1	1	1	Note 1	
	64-bit status	2	2	2	2	2	2	2	2	2	2	2	2	2	2		
# of Don't Care cycles:	3	3	3	3	3	3	3	3	3	3	3	3	3	2	1	0	0

**NOTE:**

1. Status transfer occurs on one or two subsequent IX Bus cycles.

In both 32-bit and 64-bit modes, all of the associated FBE\_L signals (FBE\_L[7:4] in 32-bit mode and FBE\_L[7:0] for 64-bit mode) are driven low on a transmit. The last bus transfer, identified by the assertion of EOP in 64-bit mode or by EOP32 in 32-bit mode, indicates the number of valid bytes of this last transfer by driving only the valid FBE\_L signals.

Similarly for receive cycles, in both 32-bit and 64-bit modes, all associated FBE\_L signals must be driven low by the peripheral or MAC device. The FBE\_L signals must identify the number of valid bytes on the last transfer driven with EOP. The IXP1240 uses this information to update the RCV\_CTL register's Valid Bytes field. Driving fewer than the four or eight FBE\_Ls, except for the last transfer with EOP, may cause undefined behavior.

#### 2.4.1.1 Reset and Idle Bus Considerations

While the IXP1240 is in reset, or when the IX Bus is idle for at least 4 FCLK cycles and no bus requests are pending, the IXP1240 drives the pins listed below. This is done so that the bus is not left in a high-Z state for a prolonged period of time. This allows the designer to avoid the use of keeper resistors on the pins to maintain valid levels.

FDAT[63:0]  
 FBE\_L[7:0]  
 FPS[2:0]  
 TXASIS  
 RDYBUS[7:0]  
 RDYCTL\_L[3:0]  
 RDYCTL\_L[4]  
 EOP  
 SOP  
 EOP32  
 SOP32  
 RXFAIL

In shared IX Bus mode, pullups should be used on PORTCTL\_L[3:0], FPS[2:0], and TXASIS to maintain valid logic levels during bus exchanges.

In configurations where two IXP1240s are in Shared IX Bus Mode, the IXP1240s must be reset synchronously, preferably with the same signal driving RESET\_IN\_L. During reset, the IXP1240s drive the pins listed above to identical logic states thereby avoiding logic state contention. If the two devices are not reset synchronously, bus contention could result if one of the devices is held in reset while the alternate device assumes the role of initial IX Bus owner and begins driving transactions. This would result in obvious bus malfunction, and over time could affect device reliability due to resulting high current conditions in the device.

## 2.5 SDRAM and SRAM Units

The IXP1240 supports two high performance memory units. The SRAM Unit provides fast memory that can be used to store look-up tables. The SDRAM Unit provides lower cost memory for forwarding information and transmit queues. Both units contain features that improve memory bandwidth utilization.

### 2.5.1 SDRAM Unit

The IXP1240 provides an SDRAM Unit to access low cost, high bandwidth memory for mass data storage. The StrongARM® core address space allows up to 256 Mbytes of SDRAM to be addressed. The SDRAM interface operates at half the core frequency ( $0.5 \times F_{core}$ ), providing a peak bandwidth of 928 Mbytes per second at 232 MHz.

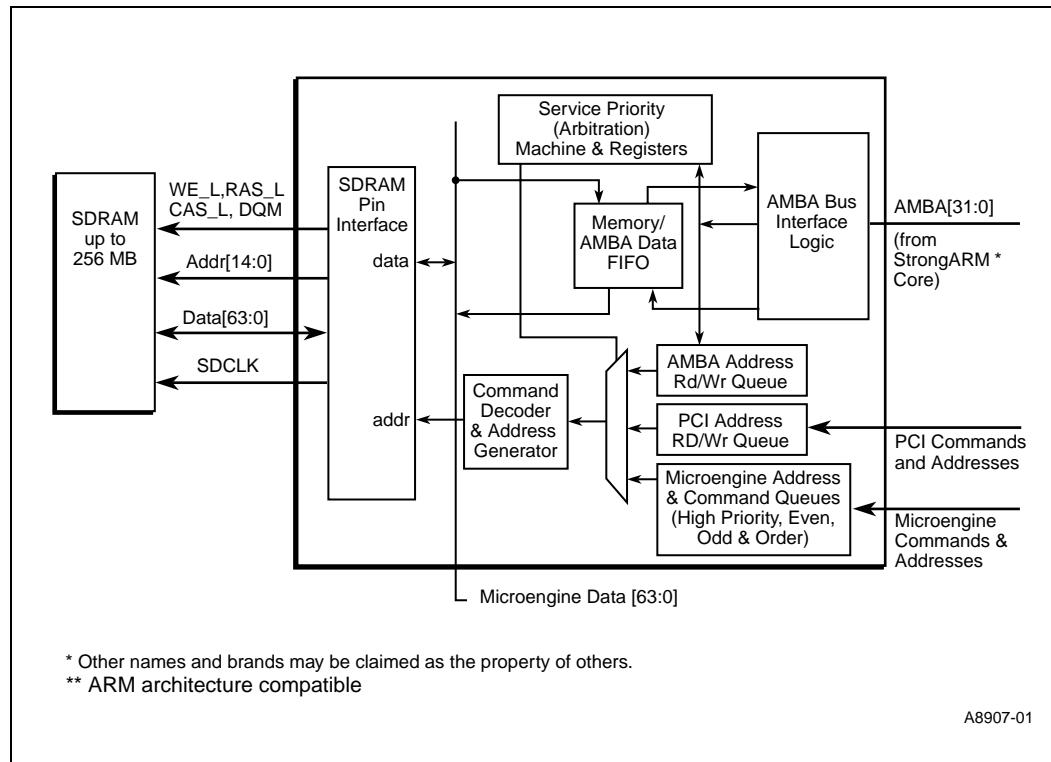

Bus cycles are generated by requests from the PCI Unit including PCI DMA cycles, the StrongARM® core, and the Microengines.

The SDRAM is operated by commands that are loaded into command queues within the unit. The SDRAM Unit decodes the command, reads or writes the data, then deletes the command from the head of the queue. The read and write sources may be SDRAM memory locations, transfer registers, or the Transmit and Receive FIFOs in the FBI Unit. Refer to the *IXP1200 Network Processor Family Hardware Reference Manual* for details on how these requests are queued, prioritized, and serviced by the SDRAM Unit.

SDRAM should have an access time ( $t_{ac}$ ) of 6 ns or less (CAS latency = 2), PC100 compatible.

Figure 3 details the major components of the SDRAM Unit.

**Figure 3. SDRAM Unit Block Diagram**

The SDRAM Bus consists of 15 row/column address bits, 64 data bits, RAS\_L, CAS\_L, write enable, DQM control, and a synchronous output clock running at one-half the IXP1240 core frequency ( $0.5 \times F_{core}$ ).

The PCI, Microengines, and StrongARM\* core require single byte, word, and longword write capabilities. The SDRAM Unit supports this using a read-modify-write technique. As data is written from the PCI or StrongARM\* core to SDRAM, a quadword is read from SDRAM. The IXP1240 then updates only the bytes that were enabled and writes the entire quadword of data back to SDRAM memory. (Note that the bytes do not have to be consecutive.) These three steps are performed automatically.

## 2.5.2

### SDRAM Bus Access Behavior

- The number of quadwords transferred by the SDRAM Unit is determined by the requesting interface (StrongARM\* core, Microengine, or PCI). The SDRAM Unit may reorder SDRAM accesses for best performance.
- Accesses are always quadword (64-bit) cycles on the SDRAM Bus.
- Accesses from the StrongARM\* core.
  - Byte, word, and longword accesses generated from the StrongARM\* core result in Read-Modify-Write cycles to SDRAM space.
  - Consecutive longword writes over the AMBA Bus to the same quadword address are buffered and aggregated into quadword writes to SDRAM.

- Read accesses using the Prefetch Memory address space allow the SDRAM Unit to prefetch quadword data to be supplied to the AMBA Bus using 32-bit burst cycles.
- Accesses from the Microengines.
  - The **sdram** microinstruction defines the number of 64-bit accesses to make, with up to 16 quadwords with one instruction.
  - Only quadword accesses are supported. Less than 8 bytes can be written when using the byte mask within an instruction, but result in Read-Modify-Write cycles.

### 2.5.3

### SDRAM Cyclic Redundancy Checking (CRC)

SDRAM Cyclic Redundancy Checking (CRC) is used to protect blocks of data called Frames. Using this technique, the transmitter appends an extra n-bit sequence (called a Frame Check Sequence or FCS) to every frame. The FCS holds redundant information about the frame that helps the transmitter detect errors in the frame.

The CRC is one of the most used techniques for error detection in data communications. The technique combines three advantages:

- Extreme error detection capabilities
- Minimal overhead
- Ease of implementation

CRC generation is performed in the SDRAM unit and is controlled by Microengine instructions. All CRC checking and appending is also handled by the Microengines.

The CRC types supported are described in [Table 5](#).

**Table 5. SDRAM CRC Types**

CRC Type	Polynomial	Application	Bit Order
CRC-32	$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$	ATM AAL5 Ethernet	MSB first LSB first
CRC-16	$X^{16} + X^{12} + X^5 + 1$	HDLC Frame Relay	LSB first LSB first
CRC-10	$X^{10} + X^9 + X^5 + X^4 + X + 1$	ATM OAM	MSB first, LW (or LW +1)

## 2.5.4 SDRAM Configurations

**Table 6. SDRAM Configurations**

Total Memory	Number of Chips	Size DRAM	Configuration (per bank)	Internal Banks	Bank Bits	RAS Bits	CAS Bits
8 Mbytes	4	16 Mbit	512 K x 16-bit	2	1	11	8
16 Mbytes	8	16 Mbit	1 M x 8-bit	2	1	11	9
32 Mbytes	4	64 Mbit	2 M x 16-bit	2	1	13	8
64 Mbytes	8	64 Mbit	4 M x 8-bit	2	1	13	9
32 Mbytes	4	64 Mbit	1 M x 16-bit	4	2	12	8
64 Mbytes	8	64 Mbit	2 M x 8-bit	4	2	12	9
64 Mbytes	4	128 Mbit	2 M x 16-bit	4	2	12	9
128 Mbytes	8	128 Mbit	4 M x 8-bit	4	2	12	10
128 Mbytes	4	256 Mbit	4 M x 16-bit	4	2	13	9
256 Mbytes	8	256 Mbit	8 M x 8-bit	4	2	13	10

## 2.5.5 SRAM Unit

The IXP1240 provides an SRAM Unit for very high bandwidth memory for storage of lookup tables and other data for the packet processing Microengines. The SRAM Unit controls the SRAM (up to 8 Mbytes), BootROM (up to 8 Mbytes) for booting, and 2 Mbytes of SlowPort address space for peripheral device access. The I/O signal timing is determined by internal address decodes and configuration registers for the BootROM and SlowPort address regions. The SRAM Unit includes an 8 entry Push/Pop register list for fast queue operations, bit test, set and clear instructions for atomic bit operations, and an 8 entry CAM for Read Locks.

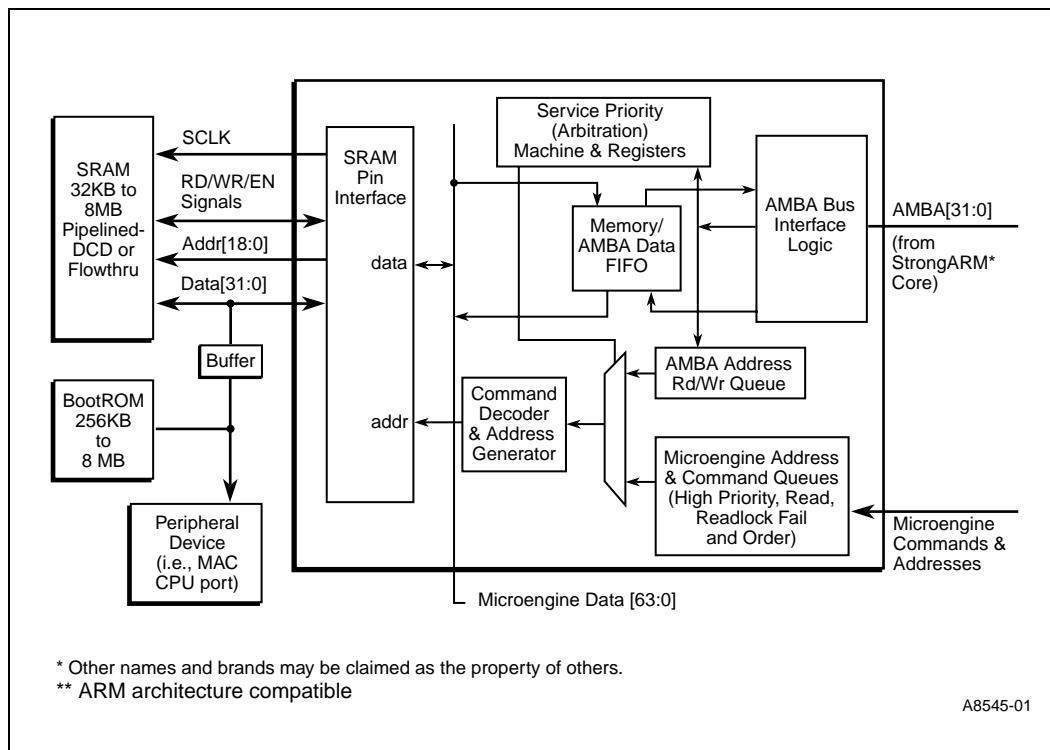

The SRAM interface operates at one-half the IXP1240 core frequency ( $0.5 * F_{core}$ ).

The SRAM Unit supports both Pipelined Burst Double Cycle Deselect (DCD) and Flowthru SRAM types. Other SSRAM devices, including single cycle deselect, are not supported. The bus is also used to attach BootROM and can be used to interface other peripheral devices such as custom interface logic or MAC management ports. The SRAM interface provides three separate timing domains for the three device types: SRAM, BootROM, and Peripheral (also referred to as SlowPort access).

BootROM devices may be either 32 bits or 16 bits in width. This is determined by GPIO[3] during reset. When 16-bit BootROM devices are used, the maximum BootROM address space is reduced from 8 Mbytes to 4 Mbytes.

Figure 4 details the major components of the SRAM Unit.

**Figure 4. SRAM Unit Block Diagram**

The SRAM Bus consists of 19 address bits, 32 data bits, 4 chip enable bits, 8 buffer and read/write control signals, a synchronous output clock (SCLK) running at one-half the IXP1240 core frequency, and a synchronous input clock (NA/SACLK). When using Flowthru SRAM types, it is recommended to route the SCLK signal from the SRAMs back to the NA/SACLK input. Routing this trace identically to the DQ data signals will skew the NA/SACLK slightly to track the return data trace propagation delay. When using Pipelined/DDC SRAMs, the NA/SACLK input is not used and may be held inactive with a pulldown to GND to save power.

The SRAM Unit receives memory requests from seven sources: the StrongARM\* core and each of the six Microengines. Refer to the *IXP1200 Network Processor Family Hardware Reference Manual* for details on the prioritization and queues provided for servicing these requests.

The IXP1240 supports the use of an optional asynchronous ready input for flexibility in interfacing memory-mapped I/O devices to the SRAM Slowport region. This will allow the I/O device to add wait-states to IXP1240 I/O accesses. This function is supported on the HIGH\_EN\_L pin. An I/O device must drive HIGH\_EN\_L with a wired-OR open drain buffer configuration, and only drive the pin when the I/O device is selected.

To use the RDY\_L pin function, it must be enabled by setting SRAM\_CSR[19]=1. The RDY\_L Pause State Value field located in register SRAM\_SLOW\_CONFIG[23:16] must be programmed with the state value at which you choose to pause the internal wait-state logic. This pause state relates to the other timing parameters programmed into the SRAM\_SLOW\_CONFIG and SRAM\_SLOWPORT\_CONFIG register fields. See [Figure 73](#) which illustrates this example. The SCC value is the total number of core clocks for the I/O cycle, and the SRWA, SCEA, SRWD, and SCED values specify the RD/WR and Chip Enable signal assert and deassert times. When the I/O cycles begins, the SCC value is loaded into the internal state counter and is decremented on each

core clock tick (twice the SCLK frequency). When the state counter reaches the RDY\_L Pause State Value, it will remain in that state until the HIGH\_EN\_L pin is sampled LOW, allowing the state counter to resume its decrement operation. The HIGH\_EN\_L must be driven for at least two SCLK periods to be sampled properly by the IXP1240.

The RDY\_L Pause State must also occur at a minimum of 5 core clock periods prior to the SRWD state to be recognized. A RDY\_L Pause State value of SRWD+5 (Decimal 10, Hexidecimal A) is used in this example.

In this example, 6 additional core clock “wait-states” are inserted. If the RDY\_L input is synchronous to SCLK and it meets the specified setup and hold times, the resulting number of wait states will be predictable. However, if the RDY\_L input is asynchronous to SCLK, the number of wait-states the IXP1240 inserts could vary +/- 2 core clock periods.

### 2.5.5.1 SRAM Types Supported

Pipeline Burst DCD (double cycle deselect) type: tKQmax=4.2 ns, 3.3 V.

Flowthru type: tKQmax= 9 ns, 3.3 V.

**Note:** Other SSRAM devices, including single cycle deselect, are not supported.

### 2.5.5.2 SRAM Configurations

**Table 7. SRAM Configurations**

Total Memory	Number of Chips (Maximum of 8)	Size of SRAM	Device Organization
1 Mbytes	8	1 Mbit	32 K x 32-bit
2 Mbytes	8	2 Mbit	64 K x 32-bit
2 Mbytes	8	2 Mbit	128 K x 16-bit
4 Mbytes	8	4 Mbit	128 K x 32-bit
4 Mbytes	8	4 Mbit	256 K x 16-bit
8 Mbytes (maximum)	8	8 Mbit	256 K x 32-bit

### 2.5.5.3 BootROM Configurations

**Table 8. BootROM x32 Sample Configurations**

Total Memory	Number of Chips (Maximum of 8)	Size of Boot ROM	Device Organization
512 Kbytes	2	2 Mbit	128 K x 16-bit
2 Mbytes	8	2 Mbit	128 K x 16-bit
4 Mbytes	8	4 Mbit	256 K x 16-bit
6 Mbytes	6	8 Mbit	512 K x 16-bit
8 Mbytes	8	8 Mbit	512 K x 16-bit

**Table 9. BootROM x16 Sample Configurations**

Total Memory	Number of Chips (Maximum of 8)	Size of Boot ROM	Device Organization
256 Kbytes	1	2 Mbit	128 K x 16-bit
512 Kbytes - 4 Mbytes	2 - 8	2 Mbit	128 K x 16-bit
512 Kbytes	1	4 Mbit	256 K x 16-bit
1 Mbytes - 4 Mbytes	2 - 8	4 Mbit	256 K x 16-bit
1 Mbytes	1	8 Mbit	512 K x 16-bit
2Mbytes - 4 Mbytes	2 - 4	8 Mbit	512 K x 16-bit

#### 2.5.5.4 SRAM Bus Access Behavior

- The SRAM controller within the IXP1240 will never initiate automatic bursting. Bursting is controlled by the requestor (StrongARM® core or Microengine) depending on the type and number of SRAM accesses needed.
- Accesses are always longword 32-bit cycles on the SRAM Bus.
- The IXP1240 always drives the address for each data cycle. No external address generation or address advance control to SRAM devices is required.
- Accesses from the StrongARM® core:
  - Byte, word, and longword accesses generated from the StrongARM® core are supported.
  - Bit operations are supported via StrongARM® core accesses to the SRAM Alias Address Space to perform the same operations as a Microengine can accomplish implicitly in a microinstruction (Push, Pop, Bit Test and Set, CAM operations, Lock/Unlock, etc.).
  - Bit, byte, and word writes result in Read-Modify-Write cycles.
  - Declare memory-mapped I/O as non-cachable to prevent line fill burst cycles, and disable caching and write buffering to ensure I/O device coherency.
  - For best performance, use longword accesses to avoid Read-Modify-Write cycles on the SRAM Bus that occur with byte and word accesses.
- Accesses from the Microengines:
  - The **sram** microinstruction defines the number of 32-bit accesses to make, up to 8 longwords with one Microengine command.
  - Only bit and longword accesses are supported.
  - Bit write accesses result in Read-Modify-Write cycles.
  - Unlike the StrongARM® core, the Microengine microinstruction allows you to perform bit operations within the instruction (Push, Pop, Bit Test and Set, CAM operations, Lock/Unlock, etc.).

## 2.6 PCI Unit

The PCI Unit provides an industry standard 32-bit PCI Bus to interface to PCI peripheral devices such as host processors and MAC devices. The PCI Unit supports operating speeds from DC up to 66 MHz, and supports *PCI Local Bus Specification, Revision 2.2*. This unit contains:

- Arbitration logic to support up to three PCI Bus masters,
- PCI Intelligent I/O (I<sub>2</sub>O),
- Two DMA channels, and
- Four 24-bit timers.

Refer to the *IXP1200 Network Processor Family Hardware Reference Manual* for details on PCI Bus behavior for Target (Slave) and Initiator (Master) modes, configuration and register definitions.

The PCI interface is specified to operate from DC up to 66 MHz. Above 33 MHz operation, two PCI devices are supported only, the IXP1240 and a second PCI device. To increase the number of PCI devices supported or to add connectors to the bus at the higher PCI Bus speeds, a PCI-to-PCI bridge device, such the Intel 21150, 21152, or 21153 is required.

Both PCI Initiator and Target cycles are supported. As a target device, the IXP1240 responds as a Medium Speed device asserting DEVSEL\_L two PCI\_CLK cycles after FRAME\_L is asserted.

### 2.6.1

#### PCI Arbitration and Central Function Support

The IXP1240 contains an optional arbiter to support up to three PCI Bus masters. This includes the IXP1240 plus two external PCI Bus master devices. The external masters are supported by two request signals, REQ\_L[1:0], and two grant signals GNT\_L[1:0].

The IXP1240 can also provide PCI Central Function support. In this configuration, the IXP1240:

- Drives the PCI Reset signal, PCI\_RST\_L, as an output,
- Monitors the PCI System Error input signal, SERR\_L, and
- Provides Bus Parking where the IXP1240 is the default PCI Bus master, and it drives valid logic levels on the PCI A/D, C/BE, and PAR pins during reset and idle PCI Bus conditions.

Two configuration pins, PCI\_CFN[1:0], are sampled at the rising edge of RESET\_IN\_L to determine the PCI configuration (see [Table 10](#)).

**Table 10. PCI Configuration Options**

PCI_CFN[1:0]	PCI FUNCTION
00	Central Function and Arbitration disabled.
10	Reserved for future use.
01	Reserved for future use.
11	Central Function and Arbitration enabled.

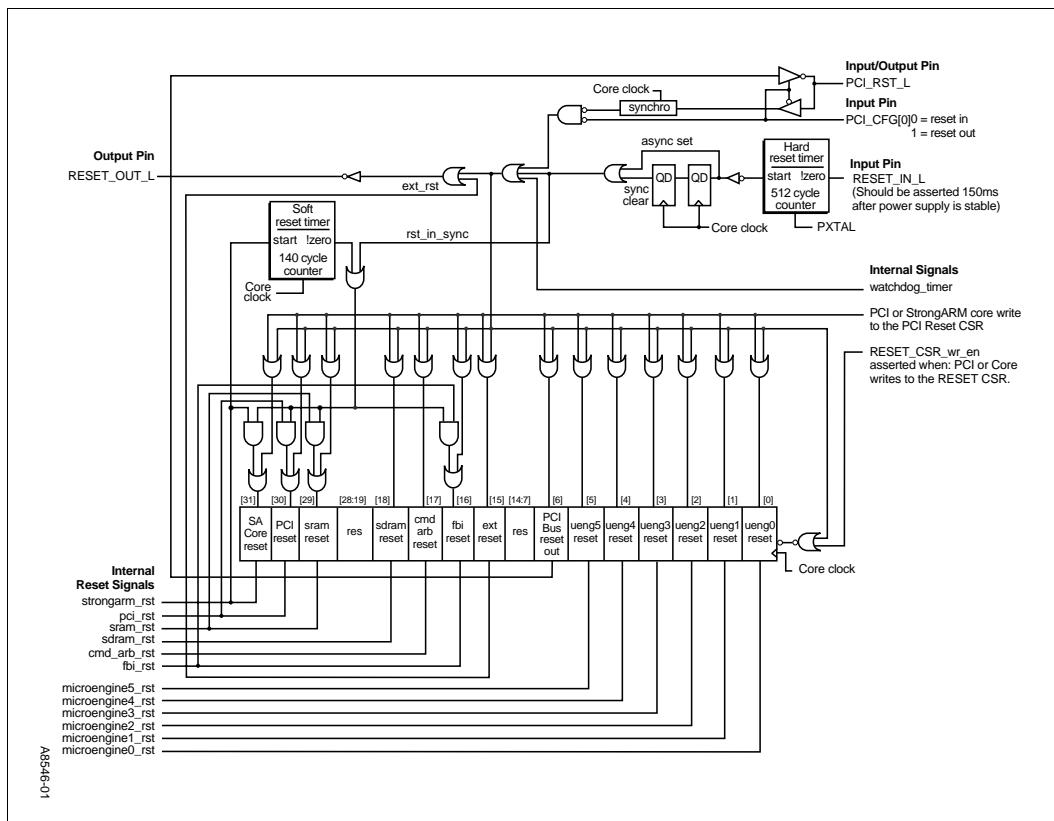

## 2.7 Device Reset

The IXP1240 can be reset by the following:

- Hardware Reset via RESET\_IN\_L pin
- Software Reset by StrongARM<sup>\*</sup> core or by PCI device write to the IXP1200\_RESET register
- PCI Reset via the PCI\_RST\_L pin
- Watchdog Timer expiration

Figure 5 illustrates details of the internal reset function logic.

**Figure 5.** Reset Logic

## 2.7.1 Hardware Initiated Reset

The IXP1240 provides the RESET\_IN\_L pin so that an external device can reset the IXP1240. Asserting this pin resets the internal functions and generates an external reset via the RESET\_OUT\_L pin.

Upon power-up, RESET\_IN\_L must remain asserted for 150 ms after VDD and VDDX are stable to properly reset the IXP1240 and ensure that the PXTAL clock input and PLL Clock generator are stable.

While RESET\_IN\_L is asserted, the processor is held reset. When RESET\_IN\_L is released, the StrongARM\* processor begins execution from SRAM address 0 after 512 PXTAL cycles. If RESET\_IN\_L is asserted while the StrongARM\* core is executing, the current instruction terminated abnormally and the on-chip caches, MMU, and write buffer are disabled.

The RESET\_OUT\_L signal remains asserted until deasserted by the StrongARM\* core. The StrongARM\* core deasserts the signal by writing bit 15 of the IXP1200\_RESET register.

## 2.7.2 Software Initiated Reset

The StrongARM\* core or an external PCI Bus master can reset specific functions in the IXP1240 by writing to the IXP1200\_RESET register. In most cases, only the individual Microengines are reset and the external RESET\_OUT\_L pin will be asserted via this register. The ability to reset the other functions is provided for debugging. The SRAM Unit is always reset when the StrongARM\* core is reset. To ensure a proper reset, the StrongARM\* core and the SRAM Unit are held in reset for 140 system clock cycles after RESET\_IN\_L is deasserted. The other functions that can be reset via the IXP1200\_RESET register are properly reset when consecutive writes are performed to assert and deassert the reset.

## 2.7.3 PCI Initiated Reset

The IXP1240 can be reset by an external PCI Bus master when the IXP1240 is not the PCI Central Function and arbiter device (PCI\_CFG[1:0] = 00) and PCI\_RST\_L is an input. The entire IXP1240 is reset during a PCI Initiated Reset. When the IXP1240 is assigned as the PCI Central Function and arbiter device (PCI\_CFG[1:0] = 11), the IXP1240 drives PCI\_RST\_L as an output to the other devices on the PCI Bus.

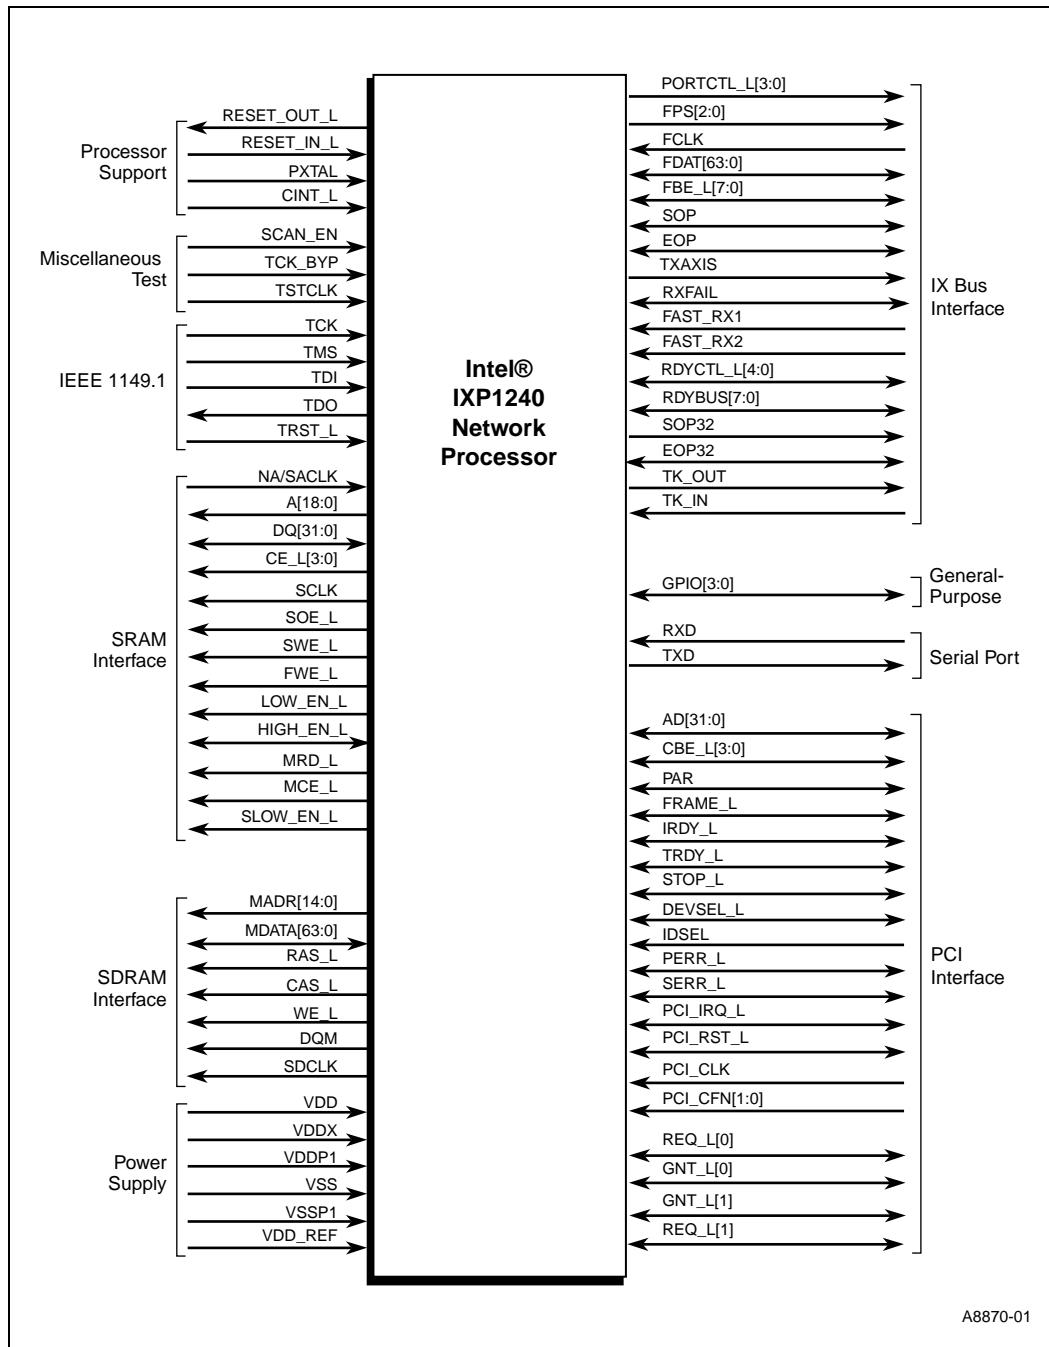

## 2.7.4 Watchdog Timer Initiated Reset

The IXP1240 provides a watchdog timer that can reset the StrongARM\* core. The StrongARM\* core should be programmed to reset the watchdog timer periodically to ensure that the timer does not expire. If the watchdog timer expires, it is assumed the StrongARM\* core has ceased executing instructions properly. The reset generated by the Watchdog Timer will reset each of the functions in the IXP1240.

## 3.0 Signal Description

### 3.1 Pinout Diagram

**Figure 6. Pinout Diagram**

## 3.2 Pin Type Legend

The IXP1240 signals are categorized into one of several groups: Processor Support, Miscellaneous/Test, IEEE 1149.1, SRAM Interface, SDRAM Interface, IX Bus Interface, General Purpose, Serial Port, and PCI Interface.

Table 11 defines the signal type abbreviations used in the Pin Description section.

**Table 11. Signal Type Abbreviations**

Signal Type	Description
I	Standard input only. There are three types of inputs (I1,I2, and I3) for the IXP1240. Refer to <a href="#">Table 35</a> and <a href="#">Table 36</a> for more information.
O	Standard output only. There are 5 types of outputs (O1,O2,O3,O4, O5) for the IXP1240. Refer to <a href="#">Table 35</a> and <a href="#">Table 36</a> for more information.
TS	Tri-state output.
STS	Sustained tri-state. Active low signal owned and driven by one and only one agent at a time. The agent that drives this pin low must drive it high for at least one clock before letting it float. A new agent cannot start driving this signal any sooner than one clock after the previous owner tri-states it. A pullup is required to sustain the inactive state until another agent drives it, and it must be provided by the central resource (that is, on a PC board).
P	Power supply.
OD	Standard open drain allows multiple devices to share as a wire-OR. A pullup is required to sustain the inactive state until another agent drives it, and it must be provided by the central resource.

### 3.3 Pin Description, Grouped by Function

#### 3.3.1 Processor Support Pins

**Table 12. Processor Support Pins**

Processor Support Signal Names	Pin #	Type	Total	Pin Descriptions
PXTAL	B4	I1	1	Input connection for system oscillator. Typically 3.6864 MHz. Drives internal PLL clock generator.
CINT_L	Y28	I1	1	Level-sensitive interrupt input to the StrongARM® core.
RESET_OUT_L	A5	O4	1	IXP1240 System Reset Output. Asserted when: <ul style="list-style-type: none"> <li>• RESET_IN_L is asserted.</li> <li>• PCI Central Function and arbiter disabled (PCI_CFN[1:0]=00) and PCI_RST_L is asserted.</li> <li>• A soft reset is initiated.</li> <li>• The Watchdog Timer expires.</li> </ul> To deassert, write register IXP1200_RESET bit 15.
RESET_IN_L	C6	I1	1	IXP1240 System Reset Input. If asserted, the IXP1240 will reset and will assert RESET_OUT_L. If PCI Central Function and arbiter enabled (PCI_CFN[1:0]=11), PCI_RST_L output will also be asserted.
Totals:			4	

### 3.3.2 SRAM Interface Pins

**Table 13. SRAM Interface Pins**

SRAM Interface Signal Names	Pin #	Type	Total	Pin Descriptions	
A[18:0]	[18] [17] [16] [15] [14] [13] [12] [11] [10] [9] [8] [7] [6] [5] [4] [3] [2] [1] [0]	A28 B28 D27 E28 D30 D31 E29 F28 E30 E31 F29 F30 F31 G29 H28 G30 G31 H29 J28	O4	19	Address outputs
DQ[31:0]	[31] [30] [29] [28] [27] [26] [25] [24] [23] [22] [21] [20] [19] [18] [17] [16] [15] [14] [13] [12] [11] [10] [9] [8] [7] [6] [5] [4] [3] [2] [1] [0]	H30 J30 J31 K29 L28 K30 K31 L29 M28 L30 L31 M29 N28 M30 M31 N29 N30 N31 P29 R28 P30 R29 R30 R31 T28 T29 T30 T31 U29 U28 V30 V29	I1/O4	32	32 Bidirectional data signals

**Table 13. SRAM Interface Pins (Continued)**

<b>SRAM Interface Signal Names</b>	<b>Pin #</b>	<b>Type</b>	<b>Total</b>	<b>Pin Descriptions</b>
CE_L[3:0] [3] [2] [1] [0]	A26 B26 C26 A27	O4	4	SRAM Bus chip enable outputs. Internally decoded from SRAM address. Valid during SRAM and BootROM accesses.
SCLK	W31	O3	1	SRAM clock output - Frequency is one half the speed of the core clock ( $\frac{1}{2} * F_{core}$ ).
NA/SACLK	B24	I1	1	SRAM clock input, used to compensate for skew in data path when using Flowthru SRAMs. Must be connected to SCLK output when using Flowthru devices. Not used with Pipelined devices and should be pulled low.
SOE_L	W30	O4	1	SRAM output enable.
SWE_L	Y30	O4	1	SRAM write enable.
FWE_L	W28	O4	1	Asynchronous interface write enable (BootROM or MAC devices).
LOW_EN_L	D26	O4	1	Low order SRAM bank enable and buffer direction select for slow interface. When used as the buffer direction select: 0 = write and 1 = read.
HIGH_EN_L	C27	I1/O4	1	High-order SRAM bank enable output and Flash PROM/BootROM read enable or asynchronous Ready input from I/O devices. The pin function is determined by programming SRAM_CSR[19] =1, which enables RDY_L or SRAM_CSR[19] =0, which enables the HIGH_EN_L function. When using the RDY_L function, I/O devices must drive this signal using a wired-OR configuration, which requires a pullup resistor on this pin. Note that this pin is driven as an output until SRAM_CSR[19] is set.
SLOW_EN_L	Y29	O4	1	Slow device enable: 0 = Slow device (BootROM or SlowPort), 1=SRAM.
MCE_L	W29	O4	1	Slow asynchronous interface chip enable output.
MRD_L	Y31	O4	1	Slow asynchronous interface read enable output.
Totals:			65	

### 3.3.3 SDRAM Interface Pins

**Table 14. SDRAM Interface Pins**

SDRAM Interface Signal Names	Pin #	Type	Total	Pin Descriptions
MADR[14:0] [14] [13] [12] [11] [10] [9] [8] [7] [6] [5] [4] [3] [2] [1] [0]	AK5 AD1 AC3 AC2 AC1 AB3 AA4 AB2 AB1 AA3 AA1 Y3 W4 Y2 Y1	O4	15	Multiplexed Row/Column address outputs.
MDATA[63:0] [63] [62] [61] [60] [59] [58] [57] [56] [55] [54] [53] [52] [51] [50] [49] [48] [47] [46] [45] [44] [43] [42] [41] [40] [39] [38] [37] [36] [35] [34] [33] [32] [31] [30] [29] [28] [27] [26]	AH6 AJ5 AL4 AK4 AH5 AH2 AH1 AG3 AF4 AG2 AG1 AF3 AF2 AF1 AE3 AD4 AE2 AE1 U4 V2 U3 U2 U1 T4 T3 T2 T1 R3 R4 P2 P3 N1 N2 N3 M1 M2 N4 M3	I1/O1	64	64 Bidirectional data signals.

**Table 14. SDRAM Interface Pins (Continued)**

<b>SDRAM Interface Signal Names</b>	<b>Pin #</b>	<b>Type</b>	<b>Total</b>	<b>Pin Descriptions</b>
[25] [24] [23] [22] [21] [20] [19] [18] [17] [16] [15] [14] [13] [12] [11] [10] [9] [8] [7] [6] [5] [4] [3] [2] [1] [0]	L1 L2 M4 L3 K1 K3 J1 J2 J3 H1 H2 J4 H3 G1 G2 H4 G3 F1 F2 F3 E1 E2 F4 E3 D1 D2			
RAS_L	W2	O4	1	Row Address Select output. Precharge cycle indicated if asserted with WE_L.
CAS_L	W3	O4	1	Column Address Select output.
WE_L	W1	O4	1	Write Enable output.
DQM	V3	O4	1	SDRAM data control output. SDRAMs use this signal to enable their data buffers to drive MDATA[63:0] on reads, or enable the SDRAM to accept input data from MDATA[63:0] for writes.
SDCLK	AD2	O3	1	SDRAM Clock output. Frequency is one half the speed of the core clock ( $\frac{1}{2} * F_{core}$ ).
Totals:			84	

### 3.3.4 IX Bus Interface Pins

**Table 15. IX Bus Interface Pins**

IX Bus Signal Names	Pin #	Type	Total	Pin Descriptions
FCLK	AB30	I3	1	IX Bus Clock input. All IX Bus transfers are synchronized to this clock. Typical operating frequency 33 MHz - 104 MHz.
PORTCTL_L[3:0] [3] [2] [1] [0]	AC30 AC31 AB29 AA28	O1/TS	4	Port Control outputs. Used to select the transmit and/or receive mode for IX Bus devices, typically MAC devices. In 64-bit bidirectional IX Bus mode, this is a 4-bit bus used to indicate transmit or receive commands and device selects. In 32-bit unidirectional IX Bus mode, bits [1:0] are used to select the receive device and bits [3:2] are used to select the transmit device. In a shared IX Bus system, these pins will be tri-stated when passing ownership of the IX Bus.
FPS[2:0] [2] [1] [0]	AC29 AD31 AD30	O4/TS	3	MAC Port Select outputs. In 32-bit and 64-bit modes, these pins select one of eight MAC receive ports from the selected MAC device. See IX Bus control signal decode tables. In a shared IX Bus system, these pins will be tri-stated when passing ownership of the IX Bus.
FDAT[63:0] [63] [62] [61] [60] [59] [58] [57] [56] [55] [54] [53] [52] [51] [50] [49] [48] [47] [46] [45] [44] [43] [42] [41] [40] [39] [38] [37] [36] [35] [34] [33] [32] [31]	AC28 AD29 AE31 AE30 AF31 AF30 AF29 AG31 AG30 AF28 AG29 AH31 AH30 AH27 AK28 AL28 AJ27 AH26 AK27 AL27 AJ26 AK26 AL26 AJ25 AH24 AK25 AL25 AJ24 AH23 AK24 AL24 AJ23 AK23	I2/O5/ TS	64	IX Bus Data. One 64-bit bus in bidirectional IX Bus mode. Two 32-bit buses in unidirectional IX Bus mode where bits [63:32] are used for Transmit Data output and [31:0] are used for Receive Data input. In a shared IX Bus system, these pins will be tri-stated when passing ownership of the IX Bus.

**Table 15. IX Bus Interface Pins (Continued)**

<b>IX Bus Signal Names</b>	<b>Pin #</b>	<b>Type</b>	<b>Total</b>	<b>Pin Descriptions</b>	
[30] [29] [28] [27] [26] [25] [24] [23] [22] [21] [20] [19] [18] [17] [16] [15] [14] [13] [12] [11] [10] [9] [8] [7] [6] [5] [4] [3] [2] [1] [0]	AL23 AJ22 AH21 AK22 AL22 AJ21 AH20 AK21 AL21 AJ20 AH19 AK20 AL20 AJ19 AK19 AL19 AJ18 AH17 AK18 AJ17 AK17 AL17 AH16 AJ16 AK16 AL16 AJ15 AH15 AK14 AJ14 AL13				
FBE_L[7:0]	[7] [6] [5] [4] [3] [2] [1] [0]	AK13 AJ13 AL12 AK12 AH13 AJ12 AL11 AK11	I2/O5/ TS	8	Bidirectional Byte Enables. 64-bit bidirectional IX Bus mode. Bits [7:0] indicate transmit and receive valid bytes on FDAT[63:0]. 32-bit unidirectional IX Bus mode. Bits [7:4] are used to indicate valid transmit bytes on FDAT[63:32] and bits [3:0] are used to indicate valid receive bytes on FDAT[31:0]. In a shared IX Bus system, these pins will be tri-stated when passing ownership of the IX Bus.
TXASIS	AL10	O4/TS	1	Transmit As Is/Transmit Error output. TXASIS states are output according to values programmed in the TFIFO control field. TXASIS value driven coincident with SOP/SOP_TX signal. In a shared IX Bus system, these pins will be tri-stated when passing ownership of the IX Bus.	
RXFAIL	AK10	I1/O1/ TS	1	Receive Packet Failure. As input, asserted by a MAC device if a packet was received with errors. Mimics the behavior of EOP to terminate an IX Bus cycle. As output, driven when no receive cycle in-progress. In a shared IX Bus system, these pins will be tri-stated when passing ownership of the IX Bus.	
FAST_RX1	AH11	I1	1	Ready Input from Fast Port 0 (i.e., Gigabit port). Pulldown through 10 KOhms to VSS if not used.	
FAST_RX2	AJ10	I1	1	Ready Input from Fast Port 1 (i.e., Gigabit port). Pulldown through 10 KOhms to VSS if not used.	

**Table 15. IX Bus Interface Pins (Continued)**

IX Bus Signal Names	Pin #	Type	Total	Pin Descriptions
RDYCTL_L[4]	AK6	I/O4/ TS	1	<p>In 64-bit Bidirectional IX Bus Mode:</p> <ul style="list-style-type: none"> <li>• 1-2 MAC mode: Used as an active low flow control enable for MAC 1 (GPIO[0] used as a flow control enable for MAC 0).</li> <li>• 3+ MAC mode: Used in conjunction with RDYCTL_L[3:0].</li> <li>• In a shared IX Bus system the IXP1240 Ready Bus Master drives this pin. **Table 15. IX Bus Interface Pins (Continued)**

<b>IX Bus Signal Names</b>	<b>Pin #</b>	<b>Type</b>	<b>Total</b>	<b>Pin Descriptions</b>
SOP32	AJ6	O4	1	<p>Transmit Start Of Packet Indication/Token Request Output.</p> <ul style="list-style-type: none"> <li>Output in 32-bit unidirectional IX Bus modes. SOP32 is Transmit Start of Packet output during transmit according to values programmed in the TFIIFO control field.</li> <li>64-bit bidirectional 3+ MAC shared bus mode, is IX Bus Token Request output indication when high.</li> <li>64-bit bidirectional 1-2 MAC mode, not used and should be left unconnected.</li> </ul>
EOP32	AL5	I1/O4	1	<p>Transmit End Of Packet/Token Request Input.</p> <ul style="list-style-type: none"> <li>32-bit unidirectional IX Bus modes EOP32 is Transmit End of Packet output according to values programmed in the TFIIFO control field.</li> <li>64-bit bidirectional IX Bus modes, single-chip operation, this input should be pulled high.</li> <li>In shared IX Bus mode, an input indicating IX Bus Token Request Pending from another device when high.</li> </ul>
TK_OUT	AA29	O1	1	<p>Token Output.</p> <p>Used to pass ownership of the IX Bus in a shared IX Bus system in 64-bit bidirectional IX Bus mode.</p> <p>In 32-bit unidirectional mode this bit is unused and should be left unconnected.</p>
TK_IN	AB31	I1	1	<p>Token Input.</p> <p>64-bit bidirectional IX Bus Mode: A high-to-low transition indicates that this device has been given ownership of the IX Bus in a shared IX Bus system.</p> <p>In 32-bit unidirectional mode, this input is not used and should be pulled high.</p> <p>During Reset, used to configure the device as initial IX Bus owner. 1= device is initial owner, 0= device does not own the IX Bus. TK_IN is sampled from the rising edge of RESET_IN_L.</p>
Totals:			103	

### 3.3.5 General Purpose I/Os

**Table 16. General Purpose I/Os**

General Purpose I/O Signal Names	Pin #	Type	Total	Pin Descriptions
GPIO[3:1] [3] [2] [1]	A25 B25 D24	I1/O4	3	Bidirectional General Purpose pins. 64-bit Bidirectional IX Bus mode: Accessible by StrongARM* core. Configurable as Input or Output. 32-bit Unidirectional IX Bus mode: Transmit Port Select [2:0] outputs. GPIO[3] is sampled during reset to determine if a 32-bit or 16-bit BootROM device is used. If low, enable 32-bit BootROM. If high, Enable 16-bit BootROM.
GPIO[0]	C25	I1/O4	1	Bidirectional General Purpose I/O pin. 1-2 MAC mode (Uni or Bidirectional mode): Active low Flow Control Enable output for MAC 0. 3+ MAC 64-bit Bidirectional IX Bus mode: Accessible to the StrongARM* core. Configurable as input or output. 3+ MAC 32-bit Unidirectional IX Bus mode: Active high Transmit Port Enable for an external PORTCTL_L[3:2] decoder.
Totals:			4	

### 3.3.6 Serial Port (UART) Pins

**Table 17. Serial Port (UART) Pins**

Serial Port (UART) Signal Names	Pin #	Type	Total	Pin Descriptions
RXD	D23	I1	1	UART Receive data.
TXD	C24	O1	1	UART Transmit data.
Totals:			2	

### 3.3.7 PCI Interface Pins

**Table 18. PCI Interface Pins**

PCI Interface Signal Names	Pin #	Type	Total	Pin Descriptions
AD[31:0]	[31] B20 [30] A20 [29] C19 [28] C18 [27] B18 [26] D17 [25] C17 [24] A16 [23] D16 [22] A15 [21] B15 [20] C15 [19] B14 [18] D15 [17] C14 [16] A13 [15] A10 [14] B10 [13] D11 [12] C10 [11] A9 [10] B9 [9] C9 [8] A8 [7] D9 [6] C8 [5] A7 [4] B7 [3] D8 [2] C7 [1] A6 [0] B6	I2/O2/ TS	32	Address/data. These signals are multiplexed address and data bus. The IXP1240 receives addresses as target and drives addresses as master. It receives write data and drives read data as target. It drives write data and receives read data as master.
CBE_L[3:0]	[3] B16 [2] B13 [1] C11 [0] B8	I2/O2/ TS	4	Command byte enables. These signals are multiplexed command and byte enable signals. The IXP1240 receives commands as target and drives commands as master. It receives byte enables as target and drives byte enables as master.
PAR	D12	I2/O2/ TS	1	Parity. This signal carries even parity for AD and CBE_L pins. It has the same receive and drive characteristics as the address and data bus, except that it occurs on the next PCI clock cycle.
FRAME_L	C13	I2/O2/ STS	1	FRAME_L indicates the beginning and duration of an access. The IXP1240 receives as target and drives as master.
IRDY_L	A12	I2/O2/ STS	1	Initiator ready. Indicates the master's ability to complete the current data phase of the transaction. The IXP1240 receives as target and drives as master.
TRDY_L	B12	I2/O2/ STS	1	Target ready. Indicates the target's ability to complete the current data phase of the transaction. The IXP1240 drives as target and receives as master.
STOP_L	C12	I2/O2/ STS	1	Stop. Indicates that the target is requesting the master to stop the current transaction. The IXP1240 drives as target and receives as master.

**Table 18. PCI Interface Pins (Continued)**

<b>PCI Interface Signal Names</b>	<b>Pin #</b>	<b>Type</b>	<b>Total</b>	<b>Pin Descriptions</b>
DEVSEL_L	D13	I2/O2/STS	1	Device Select. Indicates that the target has decoded its address as the target of the current access. The IXP1240 drives as target and receives as initiator.
IDSEL	C16	I2	1	Initialization Device Select. Used as Chip Select during PCI Configuration Space read and write transactions.
PERR_L	A11	I2/O2/STS	1	Parity error. Used to report data parity errors. The IXP1240 asserts this when it receives bad data parity as target of a write or master of a read.
SERR_L	B11	I2/O2/OD	1	<p>System Error. As an input, it can cause an interrupt to the StrongARM® core if the IXP1240 is selected for PCI Central Function and arbitration support (PCI_CFN[1:0]=11). As an output it can be asserted by the IXP1240 by writing the SERR bit in the PCI control register, or in response to a PCI address parity error when not providing PCI Central Function and arbitration support (PCI_CFN[1:0]=00).</p>
PCI_IRQ_L	A22	I2/O2/OD	1	<p>PCI Interrupt Request. As output, used to interrupt the PCI Host Processor. It is asserted when there is a doorbell set or there are messages on the I<sub>2</sub>O outbound post list. This is usually connected to INTA_L on the PCI Bus. As Input, It is asserted when there is a doorbell set or there are messages on the I<sub>2</sub>O outbound post list.</p>
PCI_RST_L	C21	I2/O2/TS	1	<p>PCI Reset.</p> <ul style="list-style-type: none"> <li>When providing PCI Central Function and arbitration support (PCI_CFN[1:0]=11), PCI_RST_L is an output controlled by the StrongARM® core. Used to reset the PCI Bus.</li> <li>When not providing PCI Central Function and arbitration (PCI_CFN[1:0]=00), PCI_RST_L is an input, and when asserted resets the IXP1240 StrongARM® core, all registers, all transaction queues, and all PCI related state.</li> </ul>
PCI_CLK	D20	I2	1	PCI Clock input. Reference for PCI signals and internal operations. PCI clock is typically 33 to 66 MHz.
PCI_CFN[1:0]	A24 C23	I2	2	<p>PCI Central Function and arbitration select inputs. Sampled on the rising edge of RESET_IN_L. When = 11, the IXP1240 provides the PCI Central Function and arbitration support and:</p> <ul style="list-style-type: none"> <li>PCI_RST_L is an output asserted by the PCI Unit when initiated by the StrongARM® core.</li> <li>IXP1240 provides bus parking during reset.</li> <li>SERR_L is an input that can generate an interrupt to the StrongARM® core.</li> </ul> <p>When = 00, PCI Central Function and arbitration is disabled and:</p> <ul style="list-style-type: none"> <li>PCI_RST_L is an input asserted by the Host processor.</li> <li>The IXP1240 does not provide bus parking during reset.</li> </ul> <p>Values of 10 and 01 are reserved for future use.</p>

**Table 18. PCI Interface Pins (Continued)**

<b>PCI Interface Signal Names</b>	<b>Pin #</b>	<b>Type</b>	<b>Total</b>	<b>Pin Descriptions</b>
GNT_L[0]	B21	I2/O2	1	<p>PCI Bus Master Grant 1.</p> <p>Internal PCI arbiter is enabled (PCI_CFN[1:0] = 11): Pin is an output to grant a PCI device 1 control of the PCI Bus. (The IXP1240 is PCI device 0 in this case)</p> <p>Internal PCI arbiter is disabled (PCI_CFN[1:0] = 00): Pin is an input that indicates that the IXP1240 can assert FRAME_L and become the bus master. If the IXP1240 is idle when GNT_L[0] is asserted, it parks the PCI Bus.</p>
REQ_L[0]	A21	I2/O2	1	<p>PCI Bus Master Request 1.</p> <p>Internal PCI arbiter is enabled (PCI_CFN[1:0] = 11): Pin is an input indicating an external PCI device is requesting use of the PCI Bus.</p> <p>Internal PCI arbiter is disabled (PCI_CFN[1:0] = 00): Pin is an output indicating that the IXP1240 is requesting use of the PCI Bus.</p>
GNT_L[1]	C20	I2/O2	1	<p>PCI Bus Master Grant 2.</p> <p>Internal PCI arbiter is enabled (PCI_CFN[1:0] = 11): Pin is an output to grant a PCI device 2 control of the PCI Bus (The IXP1240 is PCI device 0 in this case).</p> <p>When Internal PCI arbiter is disabled (PCI_CFN[1:0]=00, GNT_L[1] should be connected to VDDX through a pullup resistor of 10 KOhms.</p>
REQ_L[1]	D19	I2/O2	1	<p>PCI Bus Master Request 2.</p> <p>Internal PCI arbiter is enabled (PCI_CFN[1:0] = 11): This input indicates that PCI device 2 is requesting to take control of the PCI Bus.</p> <p>Is driven to an output high level when internal PCI arbiter is disabled (PCI_CFN[1:0] = 00).</p>
Totals:			54	

### 3.3.8 Power Supply Pins

**Table 19. Power Supply Pins**

Supply Signal Names	Pin #	Type	Total	Pin Descriptions
VDD		P	17	IXP1240 core supply (2V). A19, B19, B27, H31, J29, K2, L4, Y4, AA2, AA30, AA31, AC4, AD3, AD28, AE29, AG4, AG28
Total VDD pins			17	
VDDX		P	40	IXP1240 I/O supply (3.3V). A1, A31, B2, B30, C3, C29, D4, D7, D10, D14, D18, D22, D25, D28, G4, G28, K4, K28, P4, P28, V4, V28, AB4, AB28, AE4, AE28, AH4, AH7, AH10, AH14, AH18, AH22, AH25, AH28, AJ3, AJ29, AK2, AK30, AL1, AL31
Total VDDX pins			40	
VDD_REF	E4	P	1	IXP1240 3.3V reference - used to bias the ESD circuitry Can be tied directly to VDDX external to chip.
VSSP1	A4	P	1	IXP1240 PLL ground.
VDDP1	D5	P	1	IXP1240 2V PLL supply. Use decoupling capacitor between VDDP1 and VSSP1.
Total			3	
VSS		P	48	IXP1240 ground. A2, A3, A14, A17, A18, A29, A30, B1, B3, B17, B29, B31, C1, C2, C4, C28, C30, C31, D3, D29, P1, P31, R1, R2, U30, U31, V1, V31, AH3, AH29, AJ1, AJ2, AJ4, AJ28, AJ30, AJ31, AK1, AK3, AK15, AK29, AK31, AL2, AL3, AL14, AL15, AL18, AL29, AL30
Total VSS pins			48	
Total Power Supply Pins			108	

### 3.3.9 IEEE 1149.1 Interface Pins

**Table 20. IEEE 1149.1 Interface Pins**

IEEE 1149.1 Interface Pin Name	Pin #	Type	Total	Pin Description
TCK	A23	I1	1	Test Interface reference clock. This clock times all the transfers on the IEEE 1149.1 test interface.
TMS	C22	I1	1	Test Interface mode select. Causes state transitions on the test access port (TAP) controller.
TDI	B22	I1	1	Test Interface data input. The serial input through which IEEE 1149.1 instructions and test data enter the IEEE 1149.1 interface.
TDO	D21	O1	1	Test Interface data output. The serial output through which test instruction and data from the test logic leave the IXP1240.
TRST_L	B23	I1	1	Test Interface RESET. When asserted low, the TAP controller is asynchronously forced to enter a reset state, and disables the IEEE 1149.1 port. This pin must be driven or held low to achieve normal device operation.
Totals:			5	

### 3.3.10 Miscellaneous Test Pins

**Table 21. Miscellaneous Test Pins**

Processor Support Signal Names	Pin #	Type	Total	Pin Descriptions
SCAN_EN	C5	I1	1	Used for Intel test purposes only. Enables internal scan chains for chip testing. This pin should be connected to VSS through a pulldown resistor.
TCK_BYP	D6	I1	1	Used for Intel test purposes only. When high, bypasses PLL for Test/debug. Must be low for normal system operation.
TSTCLK	B5	I1	1	Used for Intel test purposes only. Used as clock input when bypassing the internal PLL clock generator. For Normal operation, this pin should not be allowed to float. It should be pulled up or pulled down through the proper value resistor.
Totals:			3	

### 3.3.11 Pin Usage Summary

**Table 22. Pin Usage Summary**

Type	Quantity
Inputs	21
Outputs	68
Bidirectional	235
Total Signal	324
Power	108
Overall Totals:	432

## 3.4 Pin/Signal List

### 3.6 IX Bus Pins Function Listed by Operating Mode

Figure 7 through Figure 11 illustrate the four IX Bus modes. Each figure shows the logic interface to one or more MAC devices and is accompanied by a pin description for the IX Bus in that mode.

**Figure 7. 64-Bit Bidirectional IX Bus, 1-2 MAC Mode**

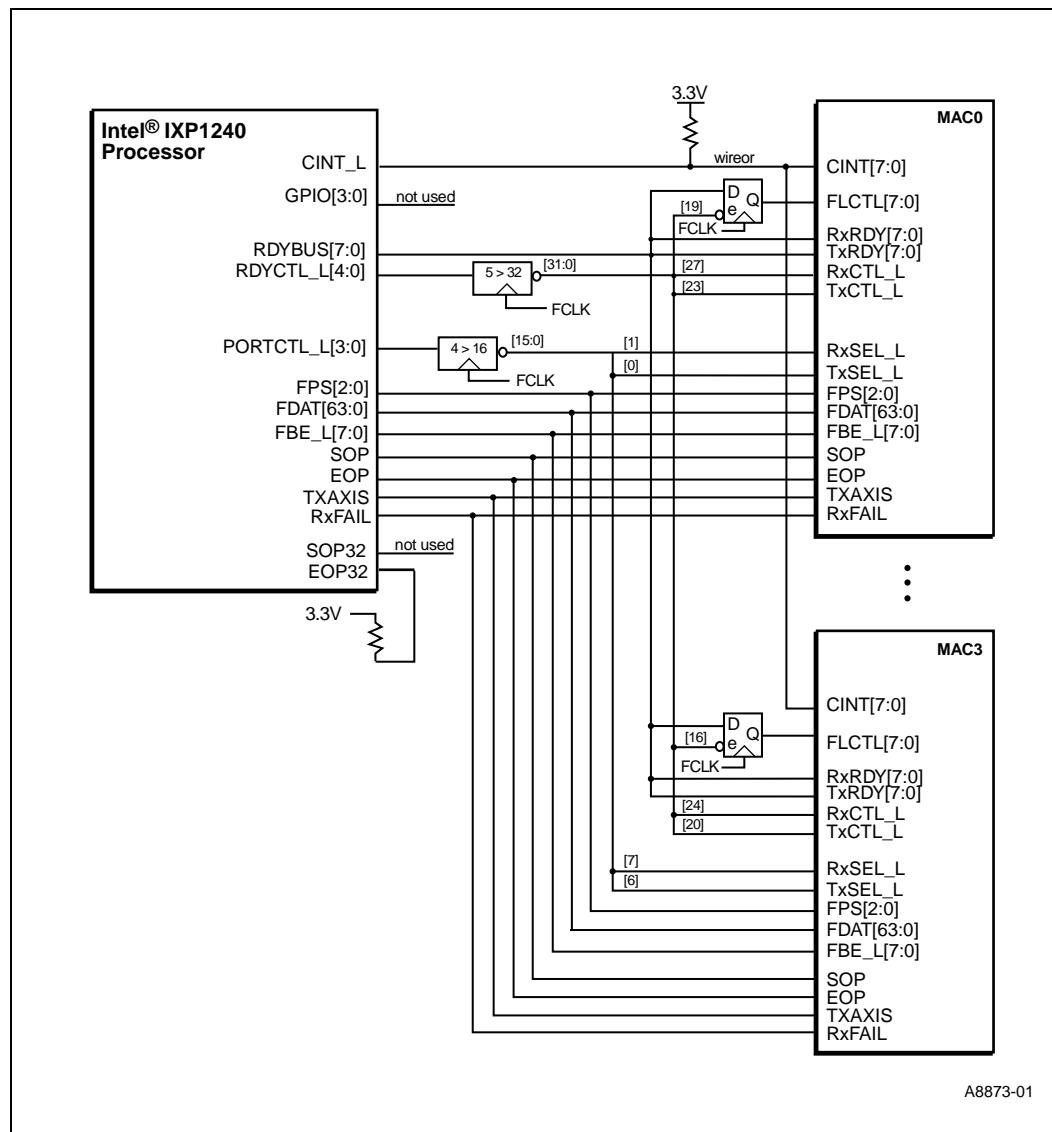

**Figure 8. 64-Bit Bidirectional IX Bus, 1-2 MAC Mode, FastPort Device**

**Table 25. 64-Bit Bidirectional IX Bus, 1-2 MAC Mode**

Signal	Description
GPIO[3:1]	Active High, input/output assigned to StrongARM* core not used for MAC interface.
GPIO[0]	Active Low, output flow-control enable for MAC 0.
RDYCTL_L[3:0]	Active Low, output, enables for Transmit or Receive Ready flags.
RDYCTL_L[4]	Active Low, output, flow-control enable for MAC 1.
RDYBUS[7:0]	Active High, input/output, Transmit or Receive Ready flags, and flow control mask data.
PORCTRL_L[3:0]	Active Low, output, transmit and receive device selects.
FPS[2:0]	Active High, output, port select.
SOP	Active High, input/output, Start of Packet indication. SOP is an output during transmit according to values programmed in the TFIFO control field. Is an input during receives indicating Receive Start of Packet from MAC.
SOP32	Output, not used, no connect.
EOP	Active High, input/output, End of Packet indication. EOP is an output during transmit according to values programmed in the TFIFO control field. Is an input during receives indicating Receive End of Packet from MAC.
EOP32	Input/output, not used, terminate through 10 KOhms to VDDX.
TK_IN	Input, not used, must be pulled High in this mode.
TK_OUT	Output, not used, no connect.
RXFAIL	Active High, input/output. Input - Receive Error input. Output - driven low during transmit and when bus maintains a No-Select state.
TXAIS	Active High, output. TXAIS states are output according to values programmed in the TFIFO Control field. TXAIS state is output coincident with SOP signal,
FBE_L[7:0]	Active Low, byte enables for FDAT [64:0].
FDAT[63:0]	Active High, read and write data.
FAST_RX1	Active High ready input from FastPort 0, pulldown 10 KOhms to GND if not used.
FAST_RX2	Active High ready input from FastPort 1, pulldown 10 KOhms to GND if not used.

**Figure 9. 64-Bit Bidirectional IX Bus, 3+ MAC Mode**

A8873-01

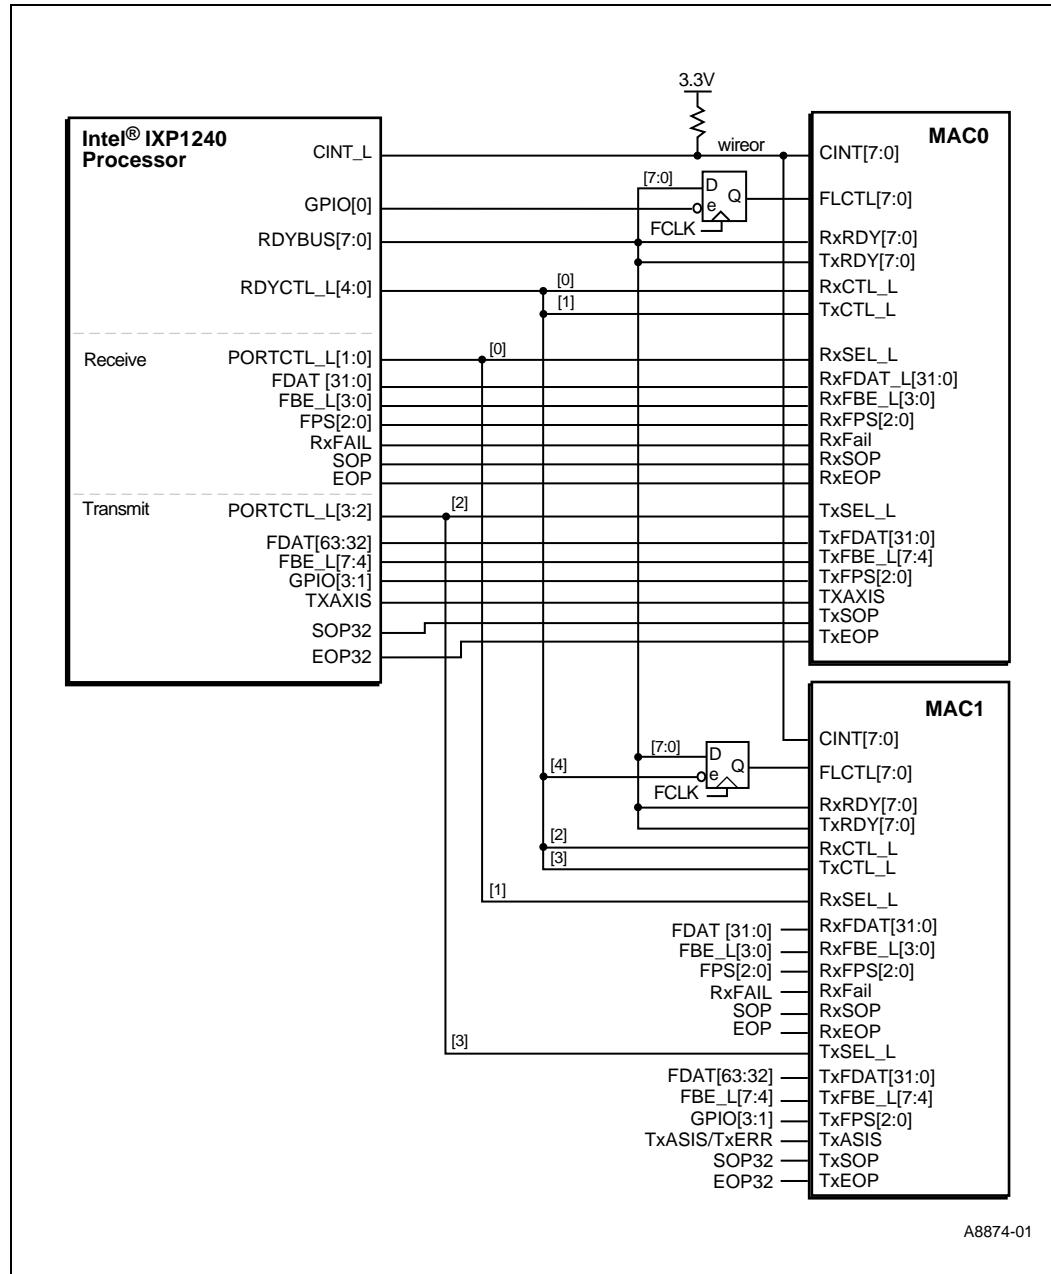

**Table 26. 64-Bit Bidirectional IX Bus, 3+ MAC Mode  
(Shared IX Bus Operation Only in This Mode)**

Signal	Description
GPIO[3:1]	Active High input/output assigned to StrongARM* core not used for MAC interface.
GPIO[0]	Active High, output assigned to StrongARM* core not used for MAC interface.
RDYCTL_L[4:0]	Output, 5 bits encoded for Transmit/Receive ready flags, flow-control, and inter-chip communication in shared IX Bus mode. Shared IX Bus mode, Initial Ready Bus master drives RDYCTL_L[4:0] and Ready Bus slave snoops.
RDYBUS[7:0]	Active High, input/output, Transmit or Receive Ready flags, flow control mask data, and inter-processor communication in shared IX Bus mode.
PORTCTL_L[3:0]	Active Low, output, 4 bits encoded for transmit and receive commands and device selects. Shared IX Bus mode - Tri-stated when the IXP1240 does not own the IX Bus.
FPS[2:0]	Active High, output, port select. Shared IX Bus mode - Tri-stated when the IXP1240 does not own the IX Bus.
SOP	Active High, input/output, Start of Packet indication. SOP is an output during transmit according to values programmed in the TFIFO control field. Is an input during receives indicating Receive Start of Packet from MAC. Shared IX Bus mode - Tri-stated when the IXP1240 does not own the IX Bus.
SOP32	Active High, output. Single chip mode - not used, no connect. Shared IX Bus mode - IX Bus Request.
EOP	Active High, input/output, End of Packet indication. EOP is an output during transmit according to values programmed in the TFIFO control field. Is an input during receives indicating Receive End of Packet from MAC. Shared IX Bus mode - Tri-stated when the IXP1240 does not own the IX Bus.
EOP32	Active High, input/output. Single chip mode - output, not used, terminate through 10 KOhms to VDDX. Shared IX Bus mode - input, IX Bus Request pending.
TK_IN	Input in Shared IX Bus mode. Single chip mode - pullup through 10 KOhms to VDDX. Shared IX Bus mode - Token_Input, enables IX Bus ownership when a high-to-low transition is detected. At reset, pull down through 10 KOhms to GND to tell the IXP1240 that it does not own the IX Bus, pull up through 10 KOhms to VDDX to set as initial IX Bus owner.
TK_OUT	Active High, output. Single chip mode - output, not used, no connect. Shared IX Bus mode - Token_Output. When high, indicates this IXP1240 owns the IX Bus.
RXFAIL	Active High, input/output. Input - Receive Error input. Output - driven low during transmit and when bus maintains a No-Select state. Shared IX Bus mode - Tri-stated when the IXP1240 does not own the IX Bus.
TXAIS	Active High, output. TXAIS states are output according to values programmed in the TFIFO Control field. TXAIS state is output coincident with SOP signal. Shared IX Bus mode - Tri-stated when the IXP1240 does not own the IX Bus.
FBE_L[7:0]	Active Low, byte enables for FDAT [64:0]. Tri-stated in shared IX Bus Mode when the IXP1240 does not own the IX Bus.

**Table 26. 64-Bit Bidirectional IX Bus, 3+ MAC Mode  
(Shared IX Bus Operation Only in This Mode) (Continued)**

Signal	Description
FDAT[63:0]	Active High, read and write data. Tri-stated in shared IX Bus mode when the IXP1240 does not own the IX Bus.
FAST_RX1	Active High ready input from FastPort 0, pulldown 10 KOhms to GND if not used.
FAST_RX2	Active High ready input from FastPort 1, pulldown 10 KOhms to GND if not used.
<b>Shared IX Bus Operation Signals</b>	
These signals are driven by the IXP1240 IX Bus owner, and are tri-stated when the IXP1240 does not own the IX Bus:	
PORTCTL_L[3:0] FPS[2:0] FDAT[63:0] FBE_L[7:0] TXASIS RXFAIL SOP EOP	

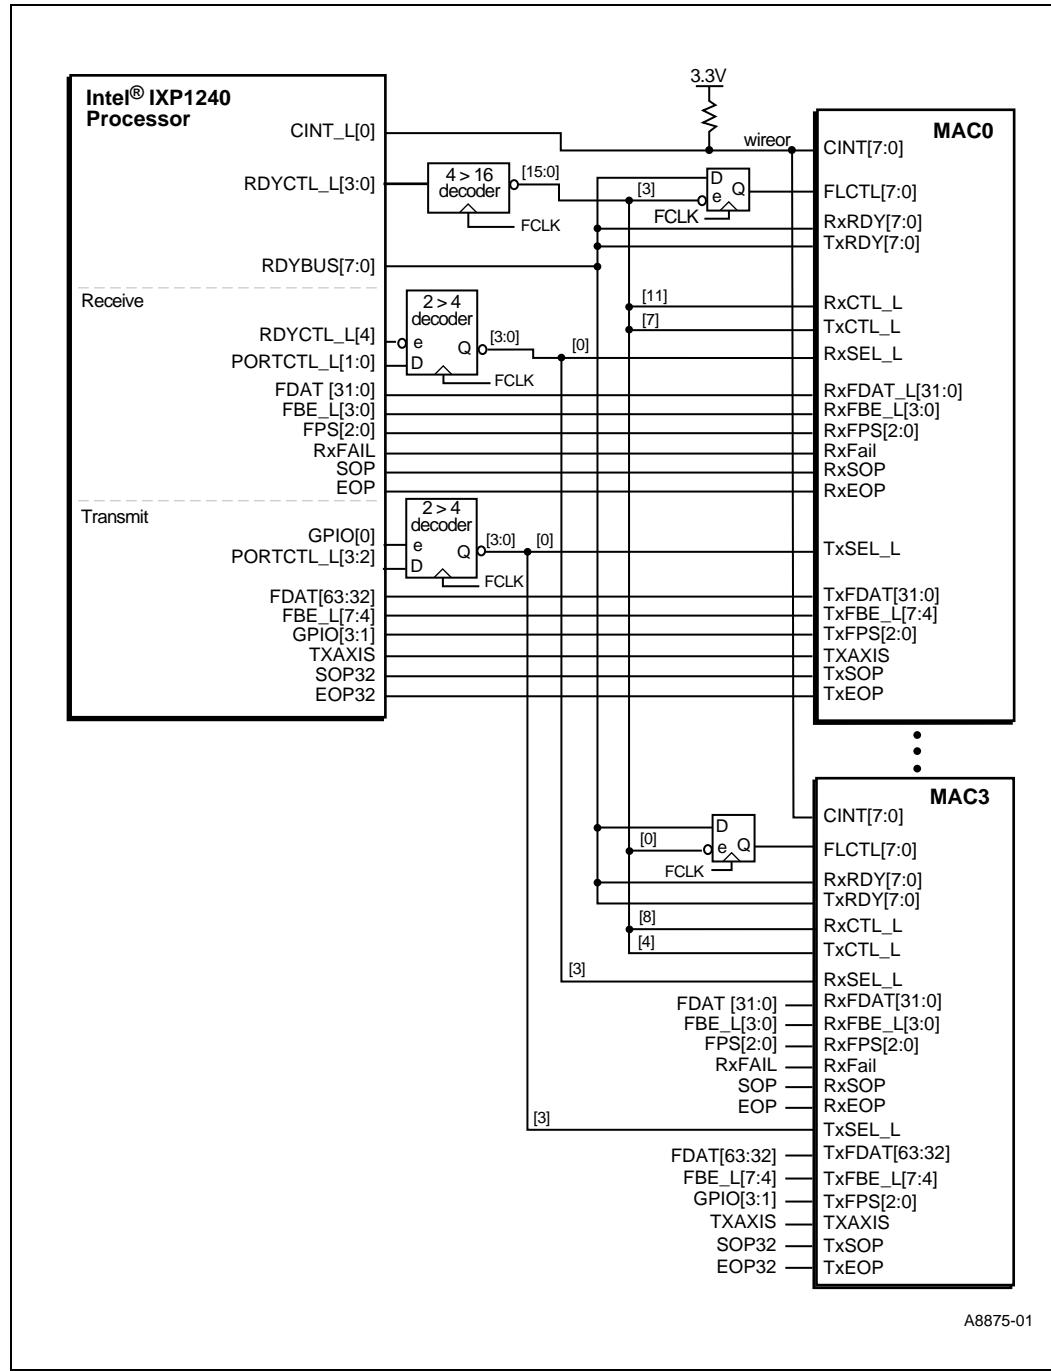

Figure 10. 32-Bit Unidirectional IX Bus, 1-2 MAC Mode

**Table 27. 32-Bit Unidirectional IX Bus, 1-2 MAC Mode**

Transmit Path Signals	Description
GPIO[3:1]	Active high outputs, Transmit Port Select [2:0].
PORCTL_L[3:2]	Active Low, output. Transmit Device Selects [1:0].
SOP32	Active High, output, transmit Start of Packet. SOP32 is output during transmit according to value programmed in the TFIFO control field.
EOP32	Active High, output, transmit End of Packet. EOP32 is output during transmit according to value programmed in the TFIFO control field.
TXASIS	Active High, output. TXASIS states are output according to values programmed in the TFIFO Control field. TXASIS state is output coincident with SOP32 signal.
FBE_L[7:4]	Active Low, output, byte enables for FDAT [63:31].
FDAT[63:31]	Active High, output, 32-bit transmit data.
Receive Path Signals	
FPS[2:0]	Active High, output. Receive Port Selects [2:0].
PORCTL_L[1:0]	Active Low, output. Receive Device Selects [1:0].
SOP	Active High, input/output, input receive Start of Packet from the MAC. Driven as output when bus remains in No-Select state.
EOP	Active High, input/output, input receive End of Packet from the MAC. Driven as output when bus remains in No-Select state.
RXFAIL	Active High, input/output, input Receive Error indication from the MAC. Driven as output when bus remains in No-Select state.
FBE_L[3:0]	Active Low, input/output, input byte enables for FDAT [31:0] from the MAC. Driven as output when bus remains in No-Select state.
FDAT[31:0]	Active High, input/output, input 32-bit receive data from the MAC. Driven as output when bus remains in No-Select state.
Control Signals Common to both Transmit/Receive Paths	
GPIO[0]	Active Low, output, flow-control for MAC 0.
RDYCTL_L[4]	Active Low, output, flow-control for MAC 1.
RDYCTL_L[3:0]	Active Low enable outputs for Transmit or Receive Ready flags.
RDYBUS[7:0]	Active High, input/output, Transmit or Receive Ready flags, and flow control mask data.
TK_IN	Input, not used, must be pulled High in this mode.
TK_OUT	Output, not used, no connect.
FAST_RX1	Active High, ready input from Fast Port 0, pulldown 10 KOhms if not used.
FAST_RX2	Active High, ready input from Fast Port 1, pulldown 10 KOhms if not used.

Figure 11. 32-bit Unidirectional IX Bus, 3+ MAC Mode (3-4 MACs Supported)

**Table 28. 32-bit Unidirectional IX Bus, 3+ MAC Mode**

Transmit Path Signals		Description
GPIO[3:1]		Active high outputs, Transmit Port Selects [2:0].
PORTCTL_L[3:2]		Active Low, outputs. Used with GPIO[0]/FC_EN0_L/TXPEN for transmit device select via external 2-to-4 decoder.
GPIO[0]		Active High, output, transmit enable. Used with PORTCTL_L[3:2] for transmit device select via external 2-to-4 decoder.
SOP32		Active High, output, transmit Start of Packet. SOP32 is output during transmit according to values programmed in the TFIFO control field.
EOP32		Active High, output, transmit End of Packet. EOP32 is output during transmit according to values programmed in the TFIFO control field.
TXASIS		Active High, output. TXASIS states are output according to values programmed in the TFIFO Control field. TXASIS state is output coincident with SOP32 signal.
FBE_L[7:4]		Active Low, output, byte enables for FDAT [63:31].
FDAT[63:31]		Active High, output, 32-bit transmit data.
Receive Path Signals		
FPS[2:0]		Active High, output. Receive Port Selects [2:0].
PORTCTL_L[1:0]		Active Low, output. Used with RDYCTL_L[4] for receive device select via external 2-to-4 decoder.
RDYCTL_L[4]		Active Low, output, receive enable. Used to enable an external 2-to-4 decoder. Used with PORTCTL_L[1:0].
SOP		Active High, input/output, input receive Start of Packet from the MAC. Driven as output when bus remains in No-Select state.
EOP		Active High, input/output, input receive End of Packet from the MAC. Driven as output when bus remains in No-Select state.
RXFAIL		Active Low, input/output, input Receive Error indication from the MAC. Driven as output when bus remains in No-Select state.
FBE_L[3:0]		Active High, input/output, input byte enables for FDAT [31:0] from the MAC. Driven as output when bus remains in No-Select state.
FDAT[31:0]		Active High, input/output, input 32-bit receive data from the MAC. Driven as output when bus remains in No-Select state.
Control Signals Common to both Transmit/Receive Paths		
RDYCTL_L[3:0]		Output, 4 bits encoded for Transmit/Receive Ready flags, flow-control, and inter-chip communication. Decode with external 4-to-16 decoder.
RDYBUS[7:0]		Active High, input/output, Transmit or Receive Ready flags, and flow control mask data.
TK_IN		Input, not used, must be pulled High in this mode.
TK_OUT		Output, not used, no connect.
FAST_RX1		Active High, ready input from Fast Port 0, pulldown 10 KOhms if not used.
FAST_RX2		Active High, ready input from Fast Port 1, pulldown 10 KOhms if not used.

IEEE 1149.1	TRST_L	input	

### 3.9

### Pullup/Pulldown and Unused Pin Guidelines

For normal (i.e., non-test mode) operation, terminate signals as follows:

- Pullup these signals to VDDX: TMS, TDI.
- TCK may be pulled up to VDDX or pulled down to VSSX at the system designer's option.
- Pulldown these signals to VSS: SCAN\_EN, TCK\_BYP, TRST\_L.
- Pullup this signal to VDDX or pulldown to VSS; do not allow it to float: TSTCLK.
- GPIO[3:1] and GPIO[0] are tri-stated during reset. If these signals are used to drive external logic, pullup or pulldown as appropriate to ensure valid logic levels during reset.

Terminate unused signals as follows:

- Pullup these signals to VDDX: GNT\_L[1], TK\_IN, EOP32.
- Pulldown these signals to VSS: NA/SACLK, FAST\_RX1, FAST\_RX2.

For shared IX Bus operation, it is recommended to pullup PORTCTL\_L[3:0] and, additionally, FPS[2:0] and TXASIS at the designer's discretion.

Typical pullup/pulldown resistor values are in the range of 5-10 KOhms.

## 4.0 Electrical Specifications

This chapter specifies the following electrical behavior of the IXP1240:

- Absolute maximum ratings.
- DC specifications.
- AC timing specifications for the following signal interfaces:
  - PXTAL Clock input.
  - PCI Bus Interface.
  - IX Bus Interface.
  - Ready Bus Interface.
  - TK\_OUT/TK\_IN signals.
  - SRAM interface.
  - SDRAM Interface.
  - Reset signals.
  - GPIO signals.
  - IEEE 1149.1 Interface.
  - Serial Port signals.

### 4.1 Absolute Maximum Ratings

The IXP1240 is specified to operate at a maximum core frequency ( $F_{core}$ ) of 232 MHz at a junction temperature ( $T_j$ ) not to exceed 100°C. [Table 31](#) lists the absolute maximum ratings for the IXP1240. These are stress ratings only; stressing the device beyond the absolute maximum ratings may cause permanent damage. Operating beyond the functional operating range ([Table 31](#)) is not recommended and extended exposure beyond the functional operating range may affect reliability.

Under all operating conditions, the 3.3 V to 2.0 V supply voltage difference ( $V_{delta}$ ) must not be exceeded or permanent damage to the device may result.

**Table 31. Absolute Maximum Ratings**

Parameter	Minimum	Maximum	Comment
Junction temperature, $T_j$	---	100°C	
Maximum voltage applied to signal pins		3.6 V	
Supply voltage (core and PLL), VDD, VDDP1	1.9 V	2.1 V	2 V supply
Supply voltage (I/O), VDDX, VDDREF	3.0 V	3.6 V	3.3 V supply
Storage temperature range	-55°C	125°C	
$V_{delta}$	0.0 V	1.8 V	(VDDX - VDD) or (VDDX - VDDP1)

The power specifications listed below are based on the following assumption:

- PCI Bus Frequency (PCI\_CLK) = 66 MHz.

**Table 32. Functional Operating Range**

Parameter	Minimum	Maximum	Comment
Operating temperature range	0°C	70°C	Tjmax to be managed to stay below 100°C. (see the Heatsink application in Figure 12).
Supply voltage (core and PLL), VDD, VDDP1	1.9 V	2.1 V	2.0 V +/- 5%
Supply voltage (I/O), VDDX, VDDREF	3.0 V	3.6 V	3.3 V +/- 10%

**Table 33. Typical and Maximum Power**

Parameter	Core Freq/IX Bus Freq 166 MHz/66 MHz		Core Freq/IX Bus Freq 200 MHz/85 MHz		Core Freq/IX Bus Freq 232 MHz/104 MHz	
	Typical <sup>1,2</sup>	Maximum <sup>1</sup>	Typical <sup>1,2</sup>	Maximum <sup>1</sup>	Typical <sup>1,2</sup>	Maximum <sup>1</sup>
2.0 V supply	3.3 W	4.8 W	3.9 W	5.4 W	4.5 W	5.9 W
3.3 V supply	0.5 W	1.2 W	0.58 W	1.2 W	0.69 W	0.8 W
Total Power	3.80 W	6.0 W	4.48 W	6.6 W	5.19 W	6.7 W

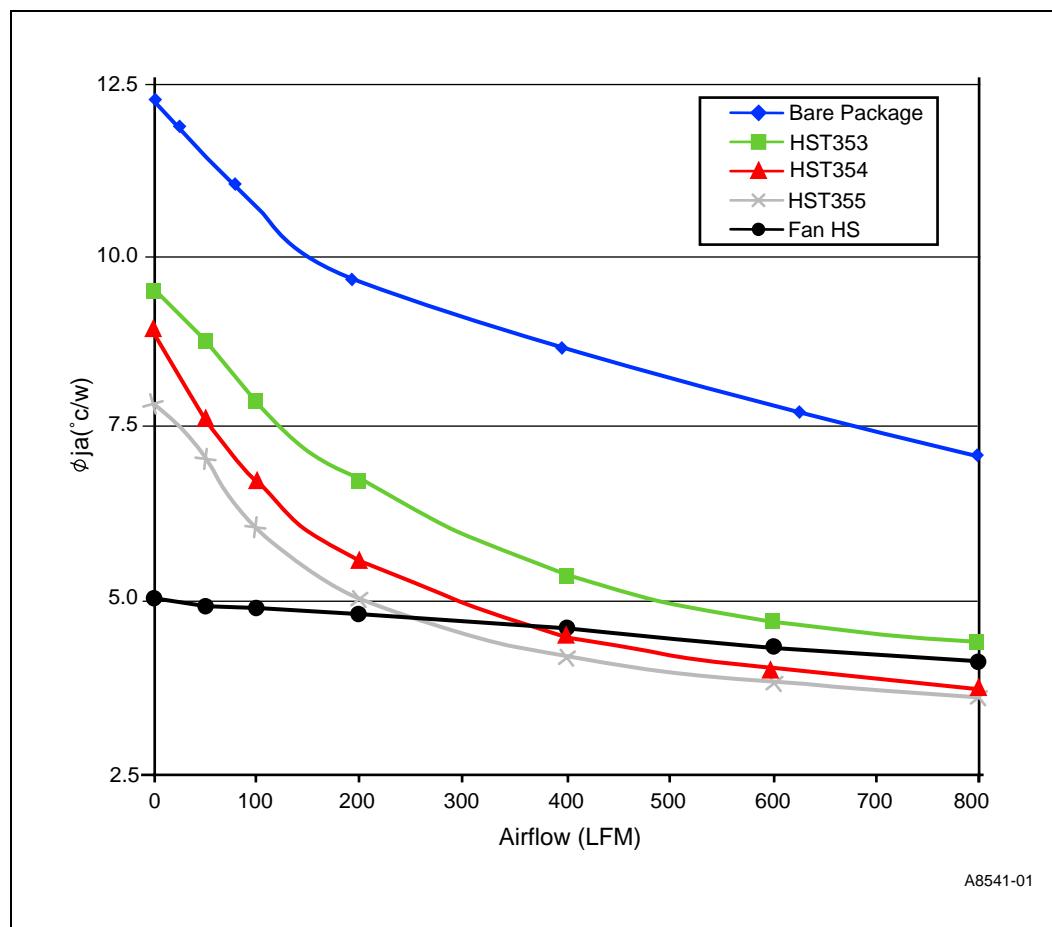

1. Typical and maximum power specifications are based upon the bus loading shown in Table 34.

2. Typical power measured at nominal supply voltages.

**Table 34. Maximum and Typical Bus Loading Used for the Power Calculations<sup>1</sup>**

	Maximum Power Load for Core Freq/IX Bus Freq 166 MHz/66 MHz	Maximum Power Load for Core Freq/IX Bus Freq 200 MHz/85 MHz	Maximum Power Load for Core Freq/IX Bus Freq 232 MHz/104 MHz	Typical Power Load for IX Bus Frequency $\leq$ 85 MHz
SDRAM Bus	8	8	5	5
SRAM Bus	8	8	5	5
IX Bus	7	4	1	2

1. A load is defined as input capacitance equivalent to a CMOS gate + minimal trace length capacitance, typically 8 pF. The customer is responsible for managing the signal integrity and external power issues that occur with increased IXP1240 Bus loading in their application to ensure reliable system operation.

**Figure 12. Typical IXP1240 Heatsink Application**

**Note:** Refer to the *IXP1200 Network Processor Heatsinks:  $\theta_{ja}$  and Airflow - Application Note* for additional information on heatsinks and thermal management.

## 4.2 DC Specifications

The IXP1240 supports two fundamental I/O buffer Types: Type 1 and Type 2. The Pin Description section defines which pins use which I/O buffer type. The driver characteristics are described in the following sections. Please note that IXP1240 input pins are not 5 V tolerant. Devices driving the IXP1240 must provide 3.3 V signal levels or use level shifting buffers to provide 3.3 V compatible levels, otherwise damage to the device will result.

The Type 1 pins are 3.3 V Low Voltage TTL compatible I/O buffers. There are three versions of the Type 1 driver that differ by the maximum available driver current.

The Type 2 pins are 3.3 V I/O buffers (supporting *PCI Local Bus Specification, Revision 2.2*).

### 4.2.1 Type 1 Driver DC Specifications

Table 35 refers to pin types: I1, O1, O3, O4, O5.

**Table 35. I1, I3, O1, O3, O4, and O5 Pin Types**

Symbol	Parameter	Condition	Minimum	Maximum
$V_{ih}$	Input High Voltage		2.0 V	---
$V_{il}$	Input Low Voltage		---	0.8 V
$V_{oh}$	Output High Voltage	O1: $I_{oh} = -2 \text{ mA}$ O3: $I_{oh} = -8 \text{ mA}$ O4: $I_{oh} = -4 \text{ mA}$ O5: $I_{oh} = -4 \text{ mA}$	2.4 V	-
$V_{ol}$	Output Low Voltage	O1: $I_{ol} = 2 \text{ mA}$ O3: $I_{ol} = 8 \text{ mA}$ O4: $I_{ol} = 4 \text{ mA}$ O5: $I_{ol} = 4 \text{ mA}$	---	0.4 V
$I_i$	Input Leakage Current <sup>1</sup>	$0 \leq V_{in} \leq V_{DDX}$	-10 $\mu\text{A}$	10 $\mu\text{A}$
$C_{in}$	Pin Capacitance	-	4 pF	10 pF

1. Input leakage currents include high impedance output leakage for all bidirectional buffers with tri-state outputs.

## 4.2.2 Type 2 Driver DC Specifications

Table 36 refers to pin types: I2, O2.

**Table 36. I2 and O2 Pin Types**

Symbol	Parameter	Condition	Minimum	Maximum
$V_{ih}$	Input High Voltage		0.5 x VDDX	VDD_REF + 0.5 V
$V_{il}$	Input Low Voltage		---	0.3 x VDDX
$V_{oh}$	Output High Voltage	$I_{oh} = -500 \mu A$	0.9 x VDDX	---
$V_{ol}$	Output Low Voltage	$I_{ol} = 1500 \mu A$	---	0.1 x VDDX
$I_i$	Input Leakage Current <sup>1</sup>	$0 \leq V_{in} \leq VDDX$	-10 $\mu A$	10 $\mu A$
$C_{in}$	Pin Capacitance		5 pF	10 pF

1. Input leakage currents include high impedance output leakage for all bidirectional buffers with tri-state outputs.

**Note:** In Table 35 and Table 36, currents into the chip (chip sinking) are denoted as positive(+) current. Currents from the chip (chip sourcing) are denoted as negative(-) current. Input leakage currents include high-Z output leakage for all bidirectional buffers with tri-state outputs. The electrical specifications are preliminary and subject to change.

## 4.2.3 Overshoot/Undershoot Specifications

The IXP1240 has been designed to be tolerant of overshoot and undershoot associated with normal I/O switching. However, excessive overshoot or undershoot of I/O signals can cause the device to latchup. Table 37 specifies limits on I/O overshoot and undershoot that should never be exceeded.

**Table 37. Overshoot/Undershoot Specifications**

Pin Type	Undershoot	Overshoot	Maximum Duration
I1/O1	-0.75 V	VDDX + 0.7 V	4 ns
I2/O2	-0.7 V	VDDX + 0.65 V	4 ns
O3	-0.7 V	VDDX + 0.6 V	4 ns
O4	-0.75 V	VDDX + 1.0 V	4 ns
O5	-0.7 V	VDDX + 0.65 V	4 ns

## 4.3 AC Specifications

### 4.3.1 Clock Timing Specifications

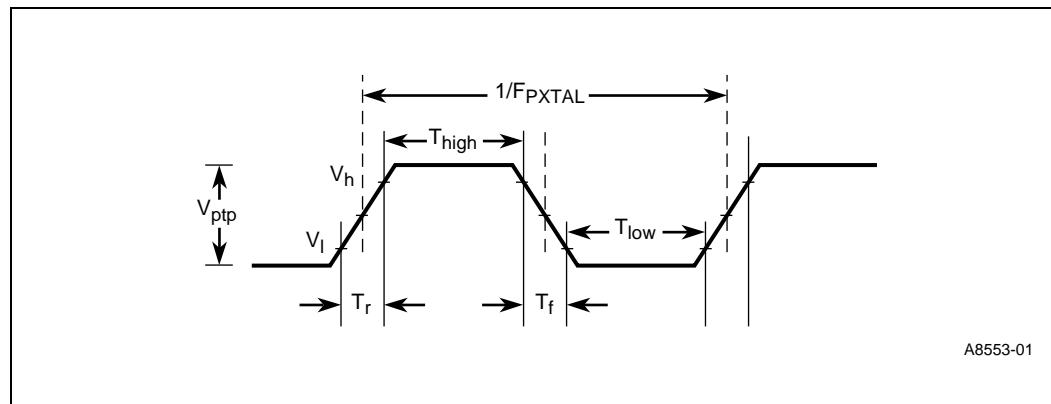

The ac specifications consist of input requirements and output responses. The input requirements consist of setup and hold times, pulse widths, and high and low times. Output responses are delays from clock to signal. The ac specifications are defined separately for each clock domain within the IXP1240.

For example, [Figure 14](#) shows the ac parameter measurements for the PCI\_CLK signal, and [Table 39](#) and [Table 40](#) specify parameter values for clock signal ac timing. See also [Figure 15](#) for a further illustration of signal timing. Unless otherwise noted, all ac parameters are guaranteed when tested within the functional operating range of [Table 32](#).

Unless otherwise indicated, all ac output delays are measured with a 5 pF load. Capacitive deratings are provided for all output buffers.

### 4.3.2 PXTAL Clock Input

**Figure 13. PXTAL Clock Input**

**Table 38. PXTAL Clock Inputs**

Symbol	Parameter	Minimum	Typical	Maximum	Unit
$F_{pXTAL}$	Clock frequency	3.5795	3.6864	3.7878	MHz
$V_{ptp}$	Clock peak to peak	0.6*VDDX	---	---	V
$V_{high}$	Clock high threshold	2.0	---	---	V
$V_{low}$	Clock low threshold	---	0.8	---	V
	Clock slew rate <sup>1</sup>	1	---	4	V/ns
$F_{core}$	Core frequency <sup>2,3,4</sup>		165.89		MHz

1. Not tested. Guaranteed by design.
2. Core frequency ( $F_{core}$ ) of 165.89 MHz when register PLL\_CFG[4:0] = 10000b.
3. Core frequency ( $F_{core}$ ) of 166.67 MHz when register PLL\_CFG[4:0] = 01111b and  $F_{pXTAL} = 3.7878$  MHz. Refer to the *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* for a complete list of programmable frequencies.
4. Core frequency ( $F_{core}$ ) of 199.0656 MHz when register PLL\_CFG[4:0] = 10011b and  $F_{pXTAL} = 3.6864$  MHz. Refer to the *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* for a complete list of programmable frequencies.

### 4.3.3 PXTAL Clock Oscillator Specifications

Frequency:	$F_{\text{pxtal}} \pm 0.01\%$
Stability:	100 ppm
Voltage signal level:	3.3 Volts
Rise/fall time:	< 4 ns
Duty cycle:	40%-60%

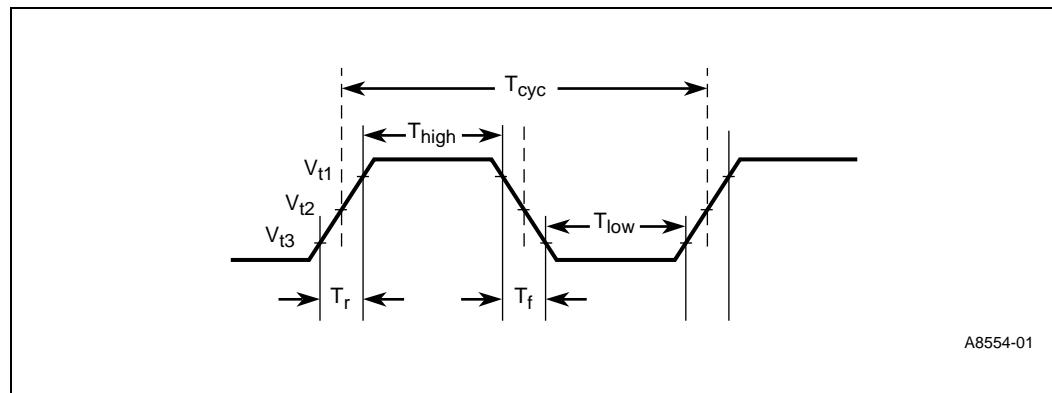

### 4.3.4 PCI

#### 4.3.4.1 PCI Electrical Specification Conformance

The IXP1240 PCI pins support the basic set of PCI electrical specifications in the *PCI Local Bus Specification, Revision 2.2*. See that document for a complete description of the PCI I/O protocol and pin ac specifications.

#### 4.3.4.2 PCI Clock Signal AC Parameter Measurements

Figure 14. PCI Clock Signal AC Parameter Measurements

$$\begin{aligned}V_{t1} &= 0.5*V_{DDX} \\V_{t2} &= 0.4*V_{DDX} \\V_{t3} &= 0.3*V_{DDX}\end{aligned}$$

Table 39. 66 MHz PCI Clock Signal AC Parameters

Symbol	Parameter	Minimum	Maximum	Unit
$T_{\text{cyc}}$	PCI_CLK cycle time	15	$\infty$	ns
$T_{\text{high}}$	PCI_CLK high time	6	---	ns
$T_{\text{low}}$	PCI_CLK low time	6	---	ns
	PCI_CLK slew rate <sup>1, 2</sup>	1.5	4	V/ns
	$F_{\text{core}}/\text{PCI Clock Ratio}$	2:1		

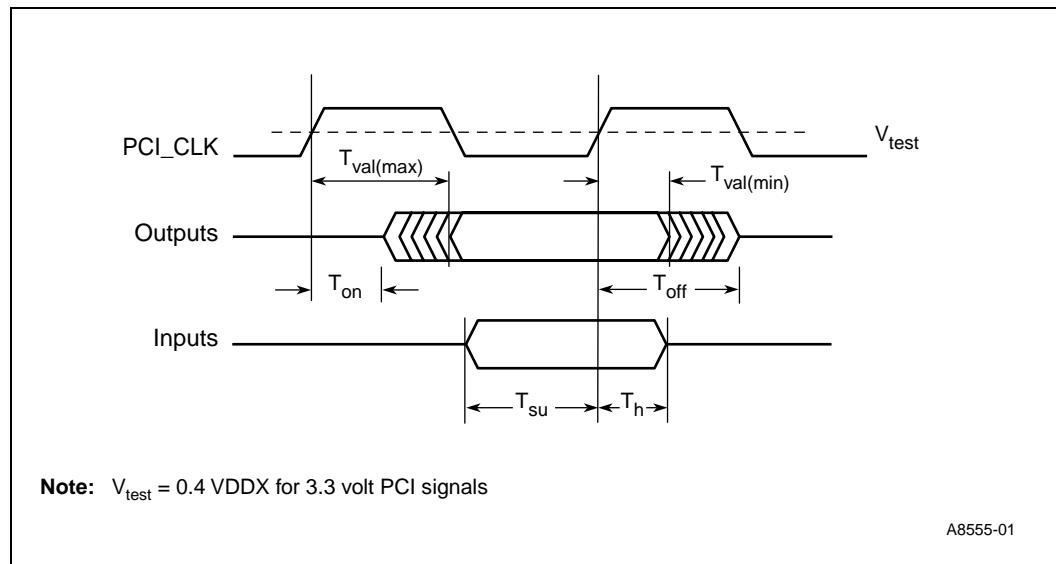

1. 0.2 VDDX to 0.6 VDDX.

2. Not tested. Guaranteed by design.

**Table 40. 33 MHz PCI Clock Signal AC Parameters**

Symbol	Parameter	Minimum	Maximum	Unit
T <sub>cyc</sub>	PCI_CLK cycle time	30	$\infty$	ns
T <sub>high</sub>	PCI_CLK high time	11	---	ns
T <sub>low</sub>	PCI_CLK low time	11	---	ns
	PCI_CLK slew rate <sup>1 2</sup>	1	4	V/ns
	F <sub>core</sub> /PCI Clock Ratio	2:1		

1. 0.2 VDDX to 0.6 VDDX.  
 2. Not tested. Guaranteed by design.

**Figure 15. PCI Bus Signals**

#### 4.3.4.3 PCI Bus Signals Timing

**Table 40. 33 MHz PCI Signal Timing**

Symbol	Parameter	Minimum	Maximum	Unit
$T_{val}^1$	CLK to signal valid delay, bused signals	1.5	11	ns
$T_{val}^1$ (point-to-point)	CLK to signal valid delay, point-to-point signals <sup>2</sup>	1.5	12	ns
$T_{on}^3$	Float to active delay	2	---	
$T_{off}^3$	Active to float delay	---	28	ns
$T_{su}$	Input setup time to CLK, bused signals <sup>2</sup>	7	---	ns
$T_{su}$ (point-to-point)	Input setup time to CLK, point-to-point signals <sup>4</sup>	10	---	ns
$T_h^1$	Input signal hold time from CLK	1	---	ns

1. These parameters are at variance with those in the *PCI Local Bus Specification, Revision 2.2*.

2. Point-to-point signals are REQ\_L, GNT\_L.

3. Not tested. Guaranteed by design.

4. Bused signals are AD, CBE\_L, PAR, PERR\_L, SERR\_L, FRAME\_L, IRDY\_L, TRDY\_L, DEVSEL\_L, STOP\_L

**Table 41. 66 MHz PCI Signal Timing**

Symbol	Parameter	Minimum	Maximum	Unit
$T_{val}^1$	CLK to signal valid delay, bused signals	1.5	7	ns
$T_{val}^1$ (point-to-point)	CLK to signal valid delay, point-to-point signals <sup>2</sup>	1.5	7	ns
$T_{on}^3$	Float to active delay	2	---	
$T_{off}^3$	Active to float delay	---	6	ns
$T_{su}$	Input setup time to CLK, bused signals <sup>4</sup>	3	---	ns
$T_{su}$ (point-to-point)	Input setup time to CLK, point-to-point signals <sup>2</sup>	5	---	ns
$T_h^1$	Input signal hold time from CLK	1	---	ns

1. These parameters are at variance with those in the *PCI Local Bus Specification, Revision 2.2*.

2. Point-to-point signals are REQ\_L, GNT\_L.

3. Not tested. Guaranteed by design.

4. Bused signals are AD, CBE\_L, PAR, PERR\_L, SERR\_L, FRAME\_L, IRDY\_L, TRDY\_L, DEVSEL\_L, STOP\_L.

### 4.3.5 Reset

#### 4.3.5.1 Reset Timings Specification

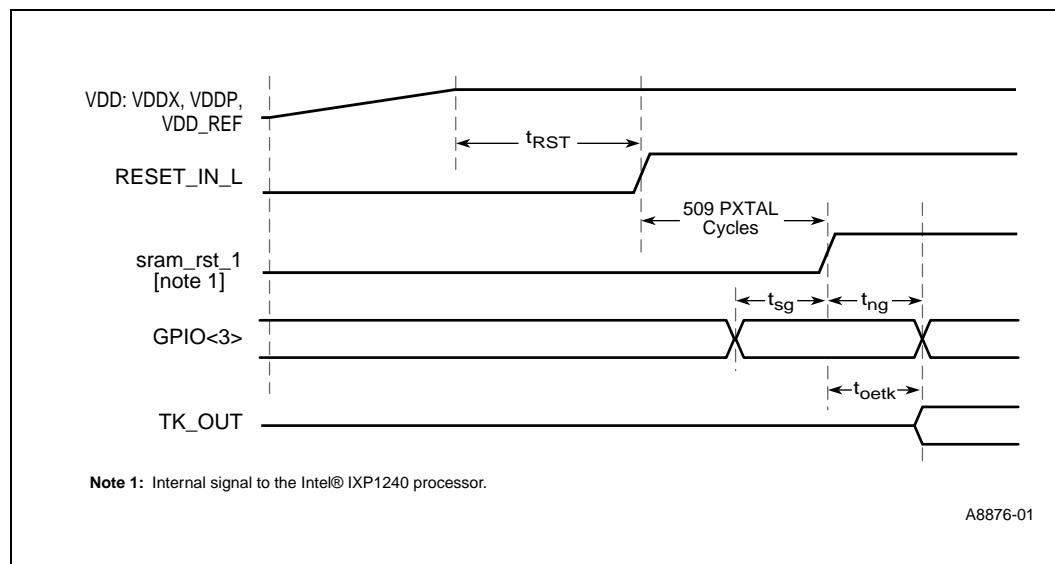

Table 42 shows the reset timing specifications for RESET\_IN\_L and RESET\_OUT\_L.

**Table 42. Reset Timings Specification**

Symbol	Parameter	Minimum	Maximum	Unit
t <sub>RST</sub>	RESET_IN_L asserted after power stable.	150	--	ms
t <sub>SG</sub>	GPIO[3] setup to reset sample edge.	2		core_clk cycles <sup>1</sup>
t <sub>HG</sub>	GPIO[3] hold from reset sample edge.	9		core_clk cycles <sup>1</sup>
t <sub>OETK</sub>	TK_OUT hi-z to valid output.	4	7	core_clk cycles <sup>1</sup>

1. core\_clk is nominally running at 29.491 MHz after a hard reset when PXTAL is 3.6864 MHz.

**Figure 16. RESET\_IN\_L Timing Diagram**

#### 4.3.6 IEEE 1149.1

The following pins are considered IEEE 1149.1 compliance pins:

RESET\_IN\_L  
PCI\_CLK  
SCAN\_EN  
TCK\_BYP  
TSTCLK

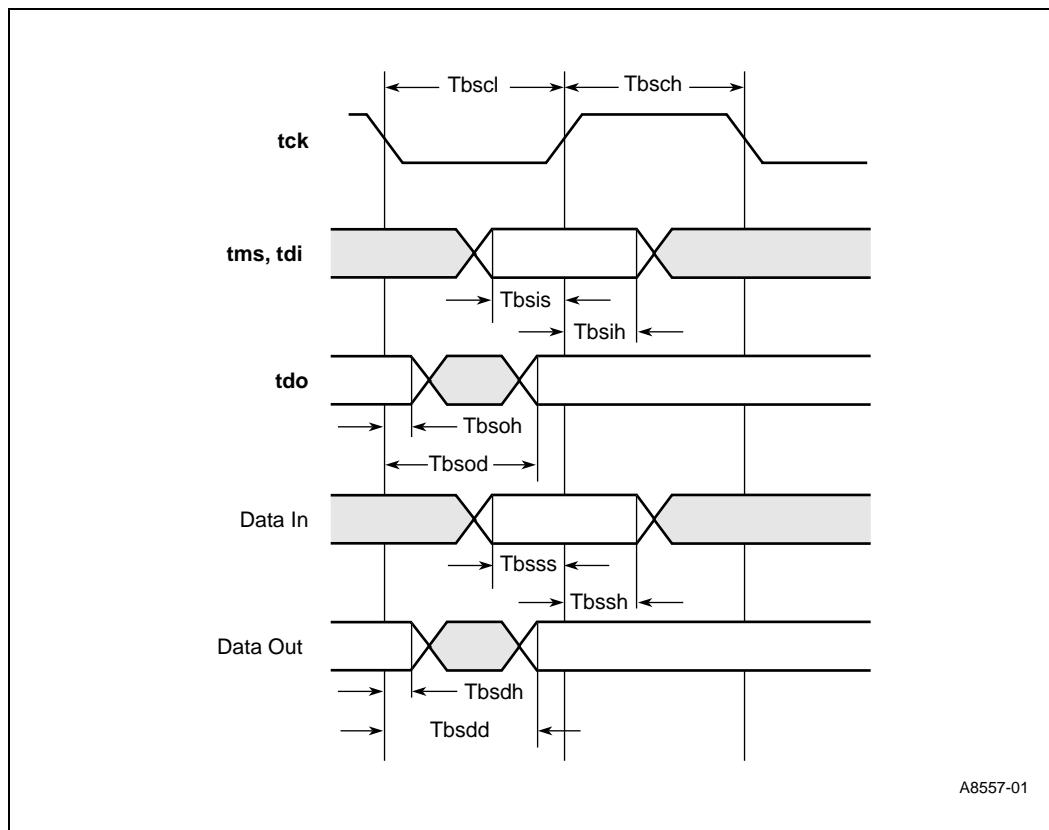

The following pins are not connected to the Boundary Scan ring:

RESET\_IN\_L  
PCI\_CLK  
SCAN\_EN  
TCK\_BYP  
TSTCLK  
TCK  
TMS  
TDI  
TDO  
TRST\_L

**Caution:** A clock signal must be applied to the core of the IXP1240 when using IEEE 1149.1 functions. The PXTAL clock input should be active, or, if using bypass mode, (TCK\_BYP = 1) TSTCLK should be active. Failure to observe this rule may cause device damage.

#### 4.3.6.1 IEEE 1149.1 Timing Specifications

Figure 17. IEEE 1149.1/Boundary-Scan General Timing

**Figure 18. IEEE 1149.1/Boundary-Scan Tri-State Timing**

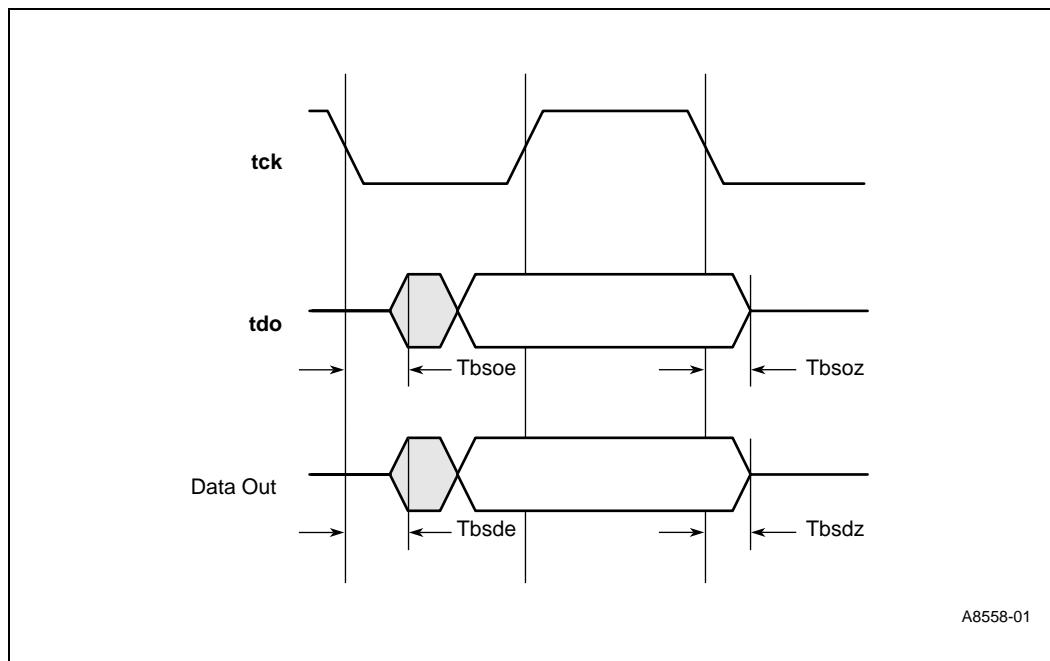

Table 43 shows the IEEE 1149.1/boundary-scan interface timing specifications.

**Table 43. IEEE 1149.1/Boundary-Scan Interface Timing**

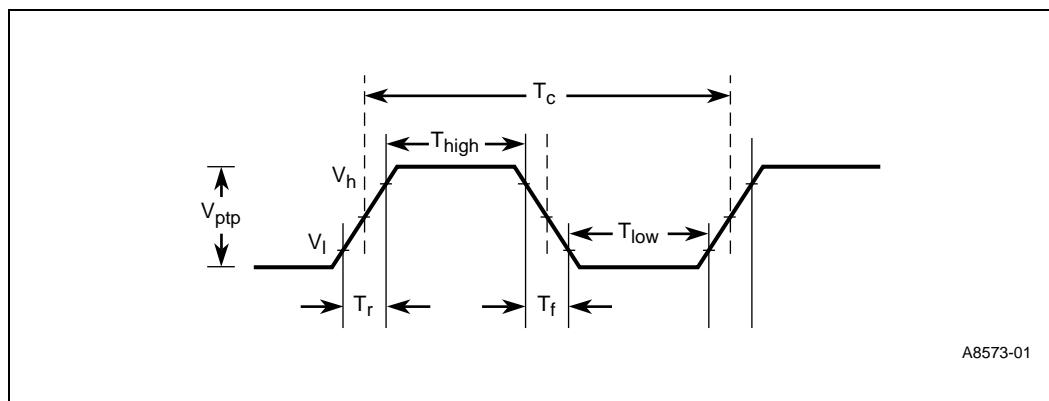

Symbol	Parameter	Minimum	Typical	Maximum	Units	Notes
Freq	TCK frequency		10		MHz	
T <sub>bscl</sub>	TCK low period	–	50	–	ns	1
T <sub>bsch</sub>	TCK high period	–	50	–	ns	1
T <sub>bsis</sub>	TDI,TMS setup time	40	–	–	ns	–
T <sub>bsih</sub>	TDI,TMS hold time	40	–	–	ns	–
T <sub>bsod</sub>	TDO valid delay	20	–	30	ns	–
T <sub>bsss</sub>	I/O signal setup time	40	–	–	ns	–
T <sub>bssh</sub>	I/O signal hold time	40	–	–	ns	–
T <sub>bsdd</sub>	Data output valid	20	–	30	ns	–
T <sub>bsoe</sub> <sup>1</sup> ,T <sub>bsoz</sub> <sup>1</sup>	TDO float delay	5	–	40	ns	–
T <sub>bsde</sub> <sup>1</sup> , T <sub>bsdz</sub> <sup>1</sup>	Data output float delay	5	–	40	ns	–
T <sub>bsr</sub>	Reset period	40	–	–	ns	–
<b>NOTES:</b>						
1. TCK may be stopped indefinitely in either the low or high phase.						

1. Not tested. Guaranteed by design.

### 4.3.7 IX Bus

#### 4.3.7.1 FCLK Signal AC Parameter Measurements

**Figure 19. FCLK Signal AC Parameter Measurements**

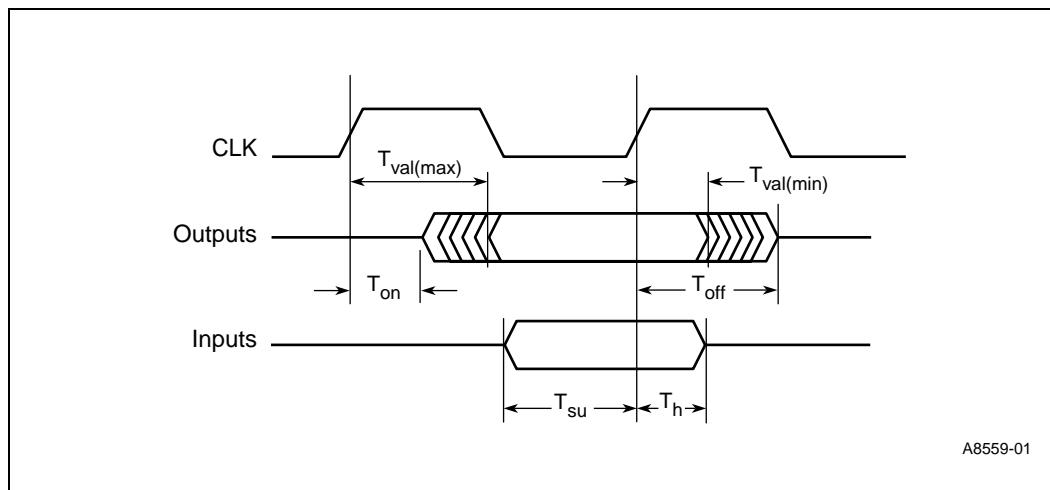

**Table 44. FCLK Signal AC Parameter Measurements**

Symbol	Parameter	Minimum	Maximum	Unit
$F_{CLK}$	Clock frequency	10	104 <sup>1</sup>	MHz
$T_c$	Cycle time	9.62 <sup>1</sup>	100	ns
$T_{high}^2$	Clock high time	3.8	---	ns
$T_{low}^2$	Clock low time	3.8	---	ns
$V_{ptp}$	Clock peak to peak <sup>2</sup>	0.6*VDDX	---	V
$T_r, T_f$	Clock rise/fall time <sup>3</sup>	1	4	ns
	$F_{core}/FCLK$ Clock Ratio	1.5:1		

1. Maximum  $F_{CLK}$  frequency for 232 MHz rated parts is 104 MHz. Maximum  $F_{CLK}$  frequency for 200 MHz rated parts is 85 MHz. Maximum  $F_{CLK}$  frequency for 166 MHz rated parts is 66 MHz.
2.  $T_{high}$  and  $T_{low}$  are based on a 50% duty cycle and can vary (worst case) 45-55%.
3. Nominal  $V_{ptp} = 0.12*VDDX$  to  $0.75*VDDX$ .

#### 4.3.7.2 IX Bus Signals Timing

**Figure 20. IX Bus Signals Timing**

**Table 45. IX Bus Signals Timing**

Symbol	Parameter	Minimum (IX Bus Speed)			Maximum (IX Bus Speed)			Unit	Condition
		66 MHz	85 MHz	104 MHz	66 MHz	85 MHz	104 MHz		
$T_{val}$	Clock to output delay	1.0	1.0	0.5	7.0	7.0	5.75	ns	0 pF load <sup>1</sup>
$T_{su}$	Data input setup time before clock	4.0	4.0	3.25	---	---	---	ns	
$T_h$	Data input hold time from clock	1.0	1.0	0.25	---	---	---	ns	
$T_{on}$	Float to FDAT[63:0] and FBE_L[7:0] data driven delay from clock <sup>2</sup>	1.5	1.5	1.5	--	--	--	ns	
$T_{onxf}$	Float to data driven from clock, excluding FDAT[63:0] and FBE_L[7:0] <sup>2</sup>	2.5	2.5	2.5	--	--	--	ns	
$T_{off}$	FDAT[63:0] and FBE_L[7:0] driven to float delay from clock <sup>2</sup>	---	---	---	7.5	7.5	7.5	ns	
$T_{offxf}$	Data driven to float delay, excluding FDAT[63:0] and FBE_L[7:0] <sup>2</sup>	---	---	---	7.0	7.0	7.0	ns	

1. Capacitive loading effects on signal lines are shown in [Table 46](#).

2. The parameter specified is guaranteed by design in a minimally configured system environment.

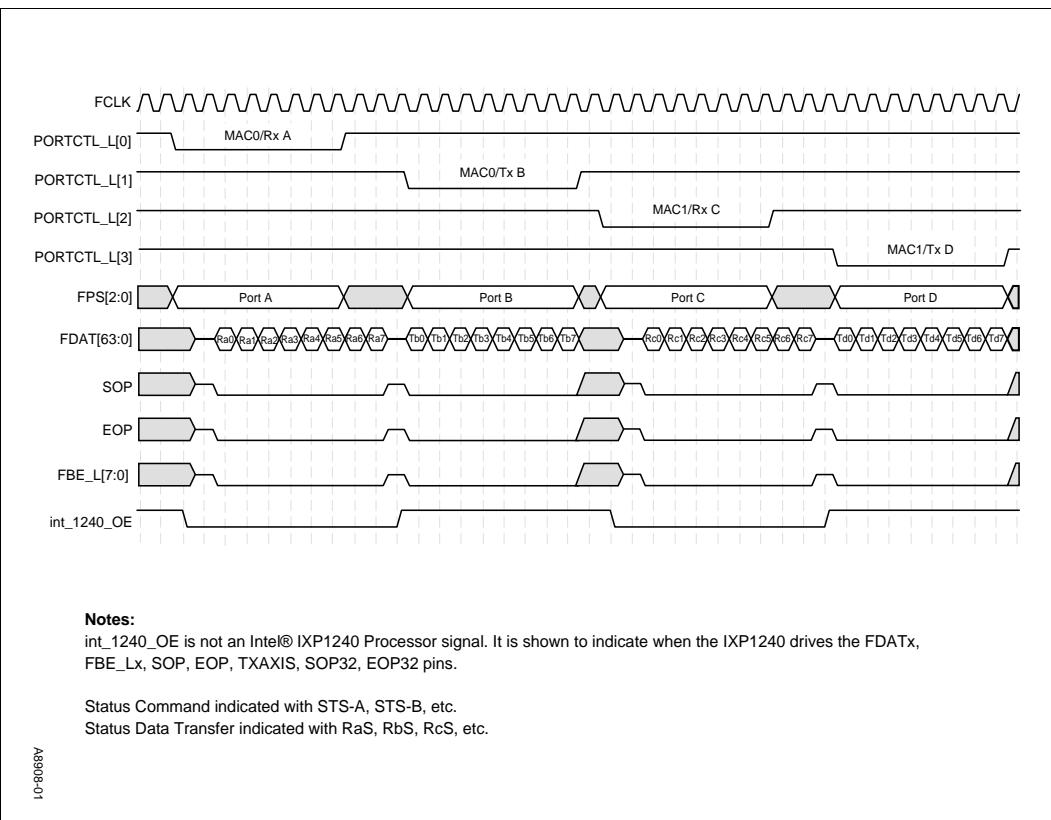

**Table 46. Signal Delay Derating**

Signal	Maximum Derating (ns/pF)			Minimum Derating (ns/pF)		
	66 MHz	85 MHz	104 MHz	66 MHz	85 MHz	104 MHz
FDATA[63:0]	0.055	0.05	0.031	0.03	0.025	0.015
FBE_L[7:0]	0.055	0.05	0.031	0.03	0.025	0.015
FPS[2:0]	0.065	0.06	0.031	0.03	0.025	0.015
TK_REQ_OUT	0.065	0.06	0.031	0.03	0.025	0.015
TK_REQ_IN	0.065	0.06	0.031	0.03	0.025	0.015
RDYCTL_L[4:0]	0.065	0.06	0.031	0.03	0.025	0.015
RDYBUS[7:0]	0.065	0.06	0.031	0.03	0.025	0.015
TXAXIS	0.065	0.06	0.031	0.03	0.025	0.015
EOP	0.065	0.06	0.031	0.03	0.025	0.015
SOP	0.065	0.06	0.031	0.03	0.025	0.015
GPIO[3:0]	0.065	0.06	0.031	0.03	0.025	0.015
PORTCTL_L[3:0]	0.095	0.09	0.035	0.03	0.025	0.015
TK_OUT	0.095	0.09	0.035	0.03	0.025	0.015
RXFAIL	0.095	0.09	0.035	0.03	0.025	0.015

#### 4.3.7.3 IX Bus Protocol

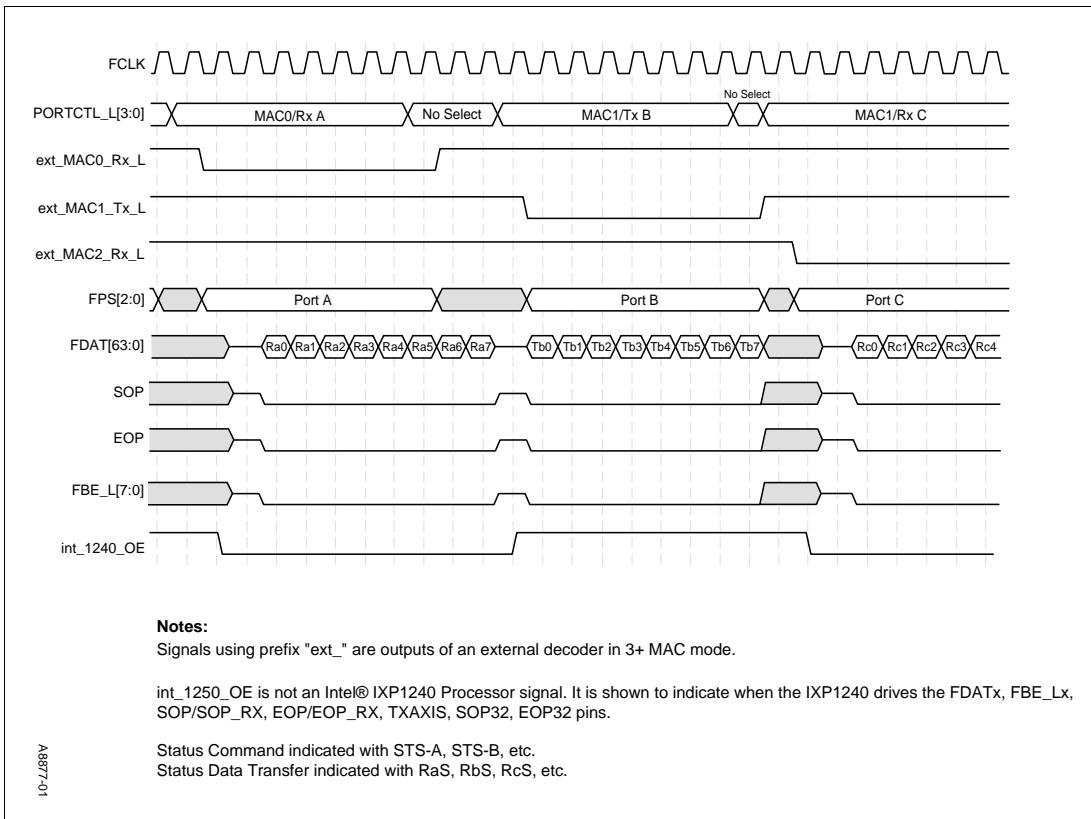

The following timing diagrams show the IX Bus signal protocol for both 64-bit Bidirectional and 32-bit Unidirectional modes of operation.

**Figure 21. 64-Bit Bidirectional IX Bus Timing, 1-2 MAC Mode, Consecutive Receive and Transmit, No EOP**

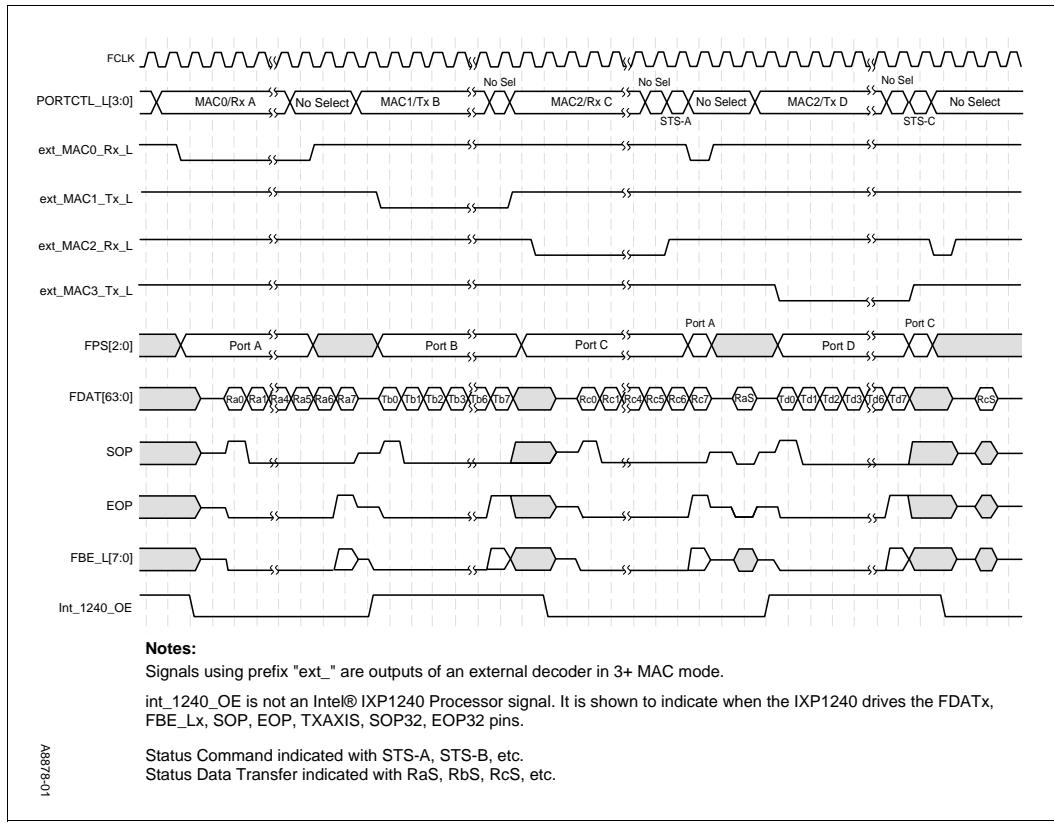

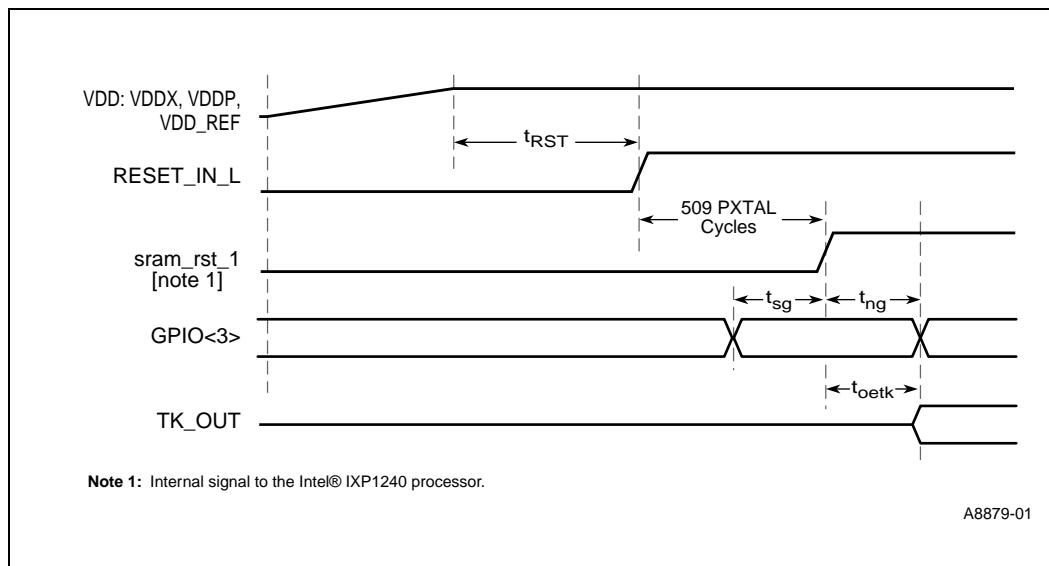

**Figure 22. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, No EOP**

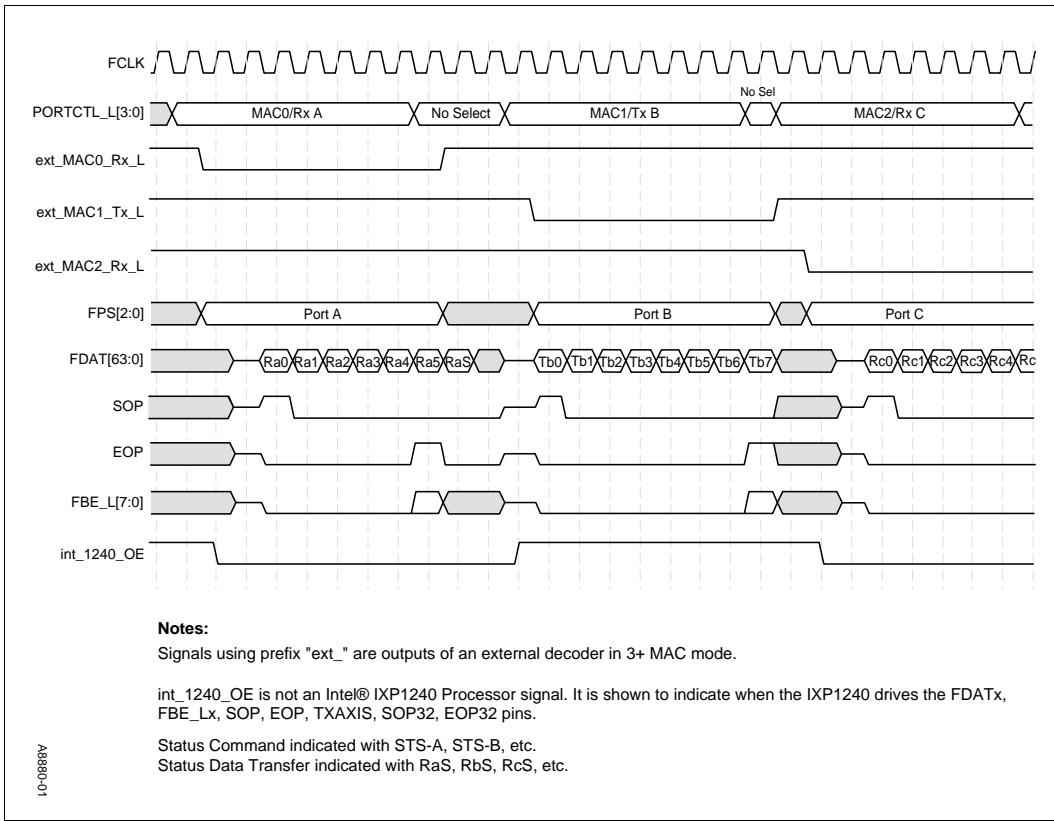

**Figure 23. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, EOP on 8th Data Return with Status**

**Figure 24. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, EOP on 7th Data Return with Status**

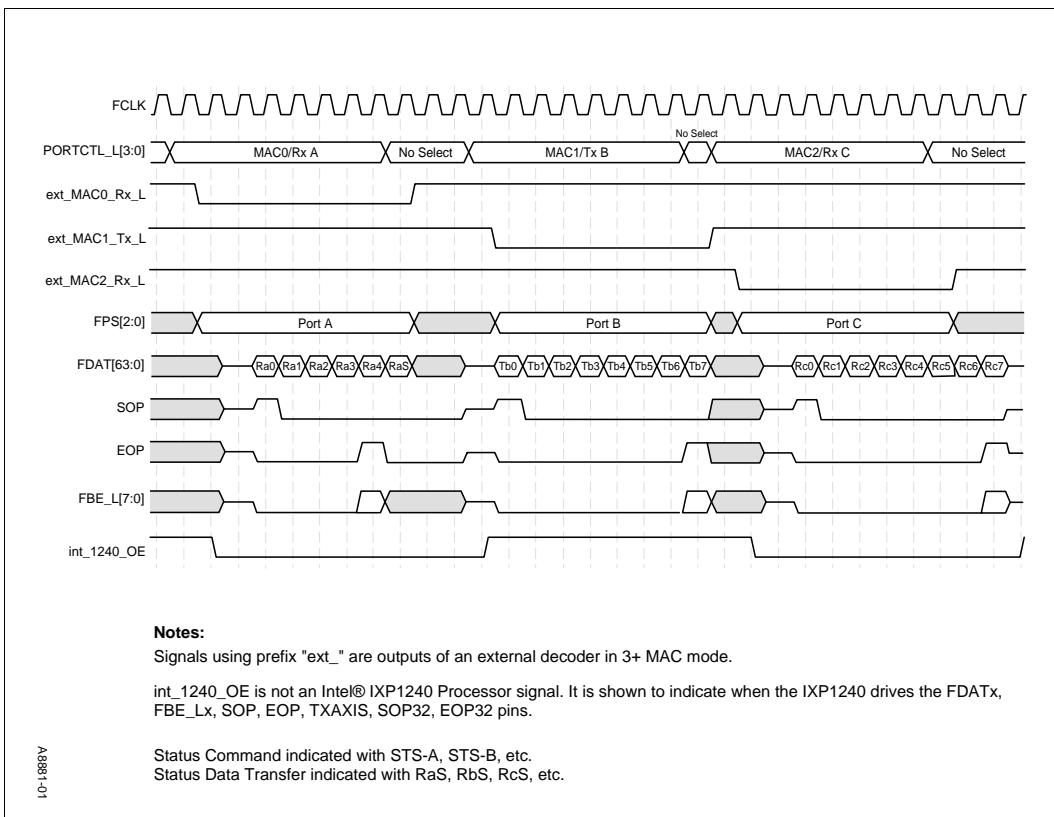

**Figure 25. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, EOP on 6th Data Return with Status**

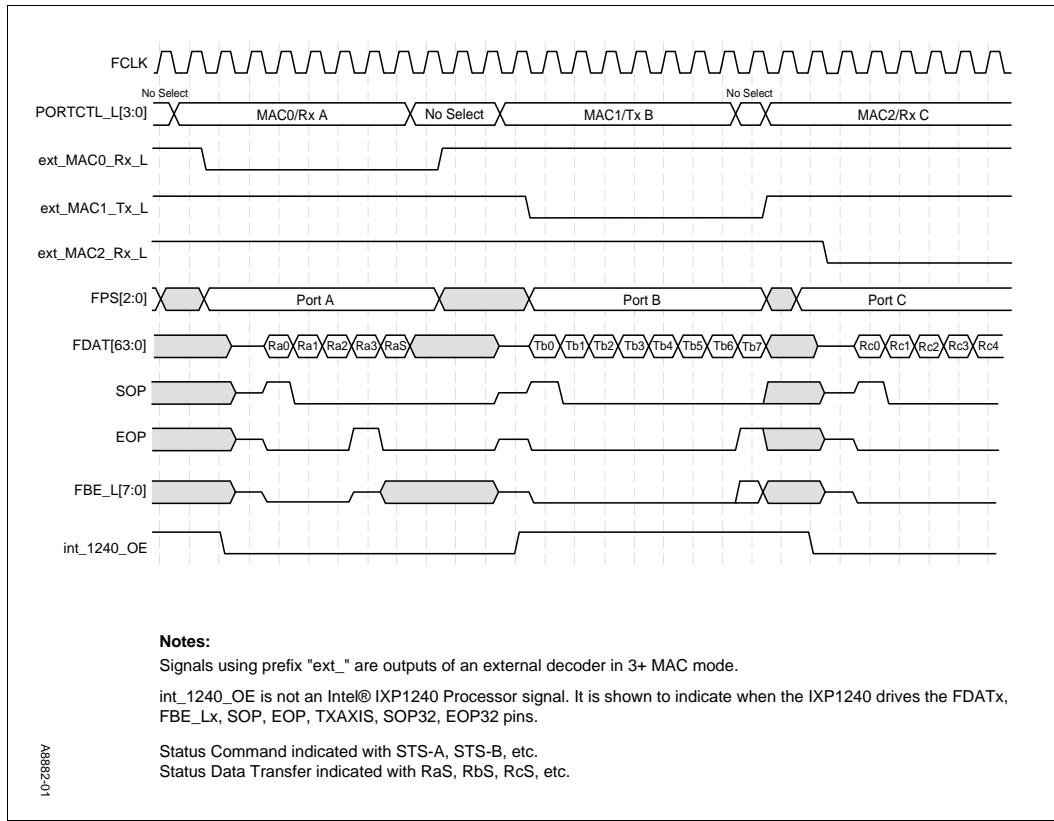

**Figure 26. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, EOP on 5th Data Return with Status**

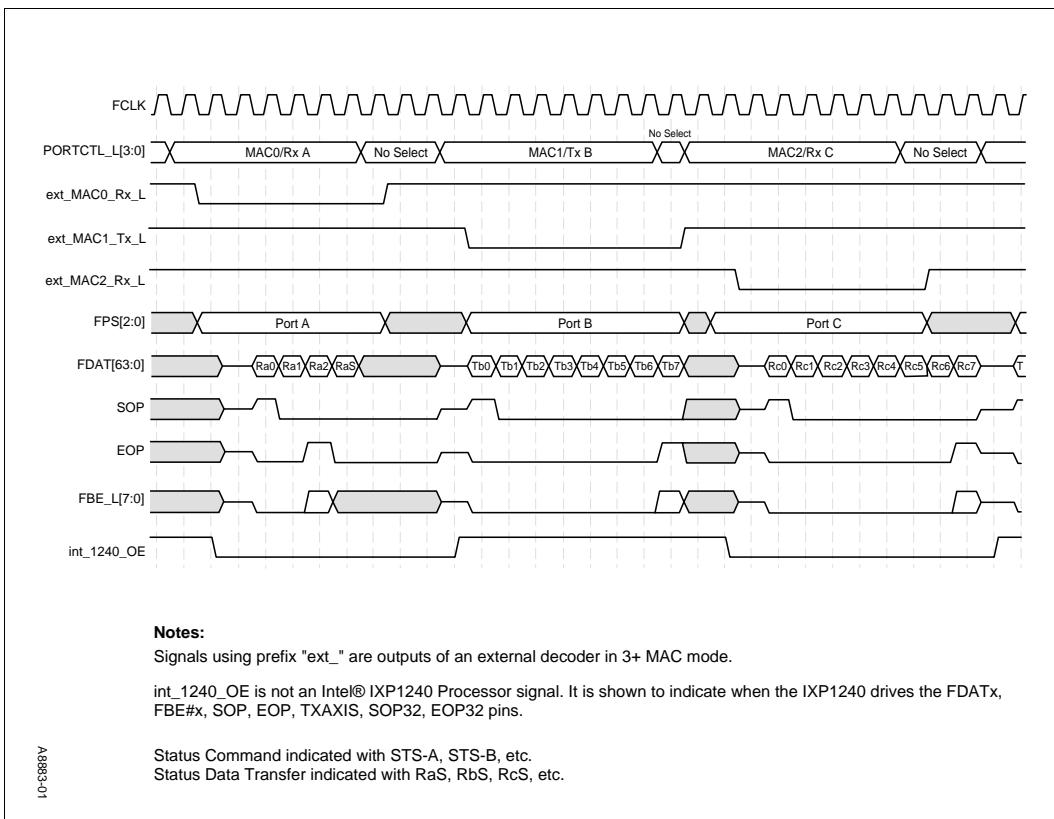

**Figure 27. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, EOP on 4th Data Return with Status**

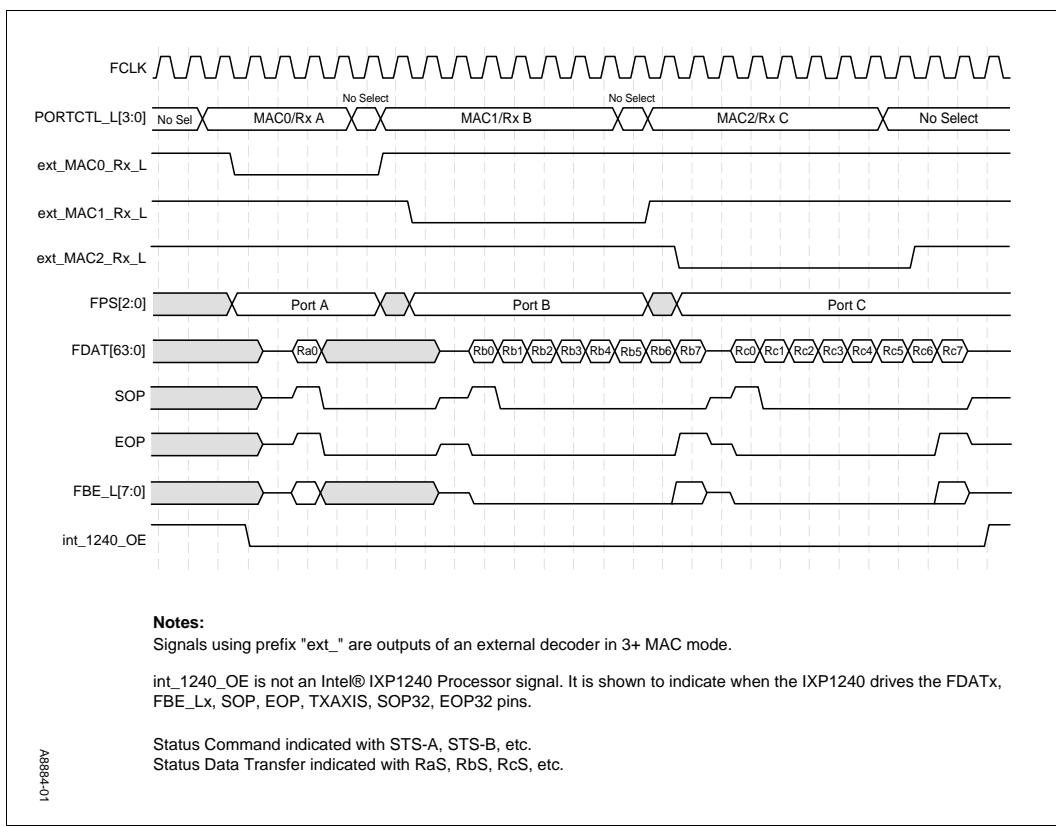

**Figure 28. 64-Bit Bidirectional IX Bus Timing - Consecutive Receive and Transmit, EOP on 1st through 3rd Data Return with Status (3rd Data Return Shown)**

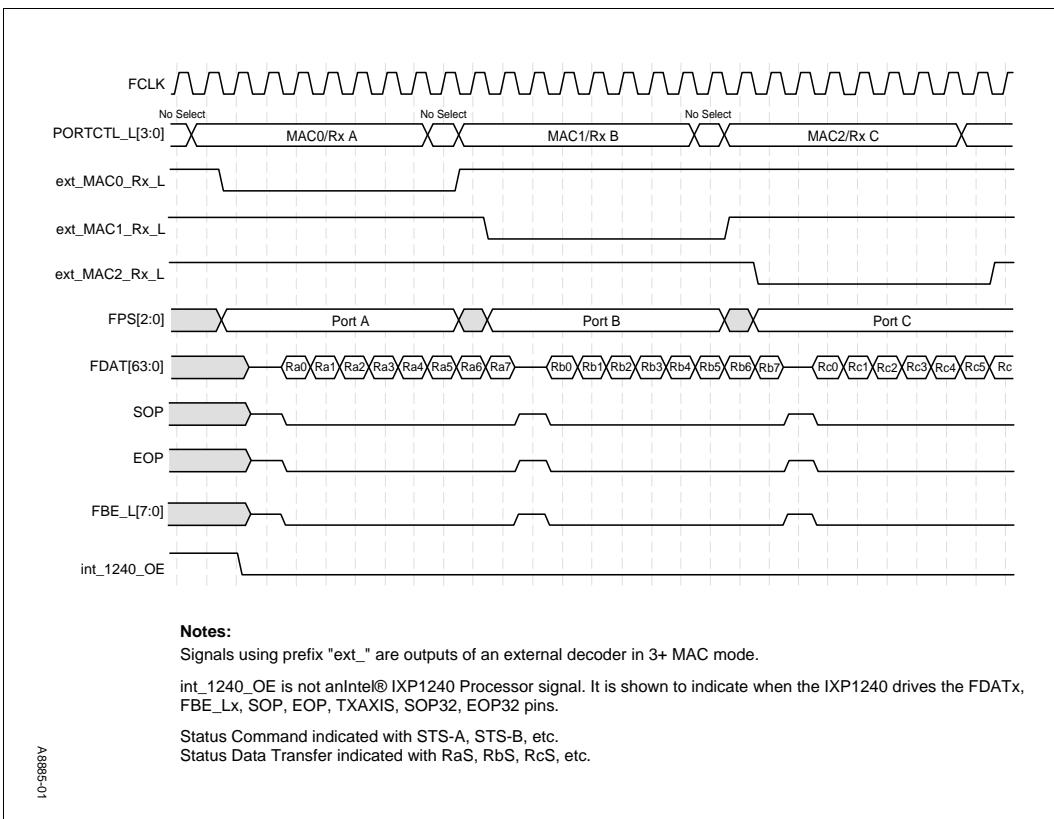

**Figure 29. 64-Bit Bidirectional IX Bus Timing - Consecutive Receives, EOP on 1st Data  
Return, No Status**

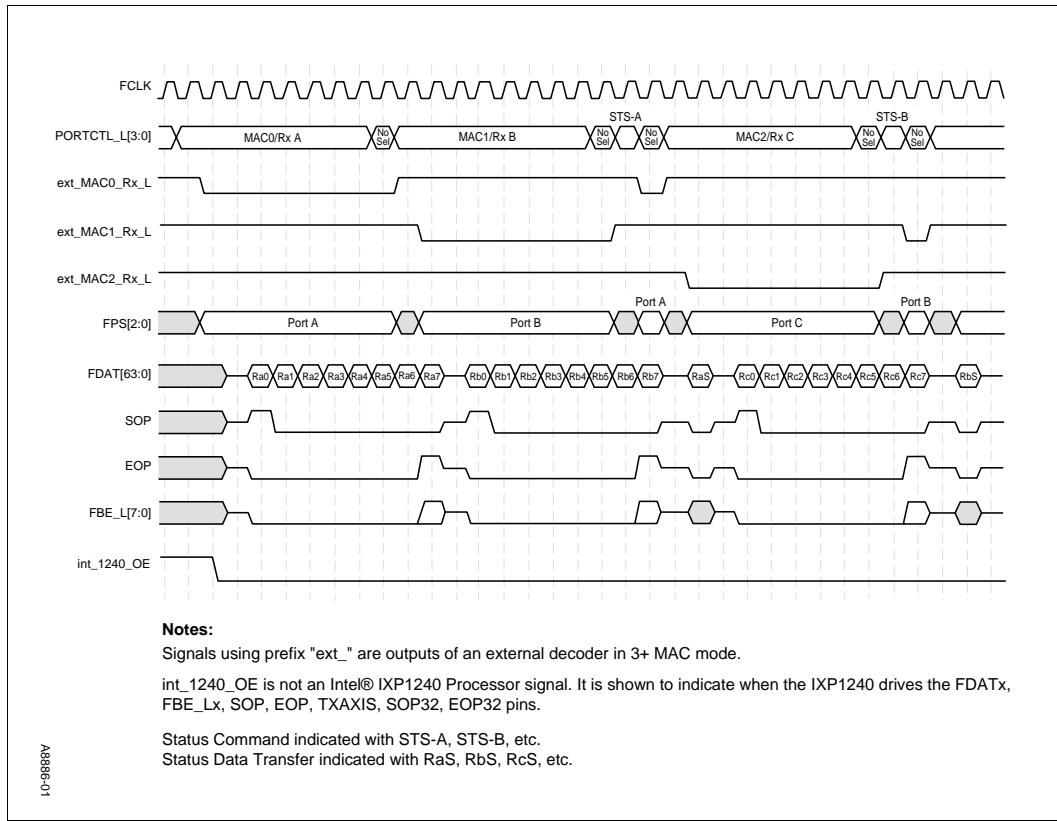

**Figure 30. 64-Bit Bidirectional IX Bus Timing - Consecutive Receives, No EOP**

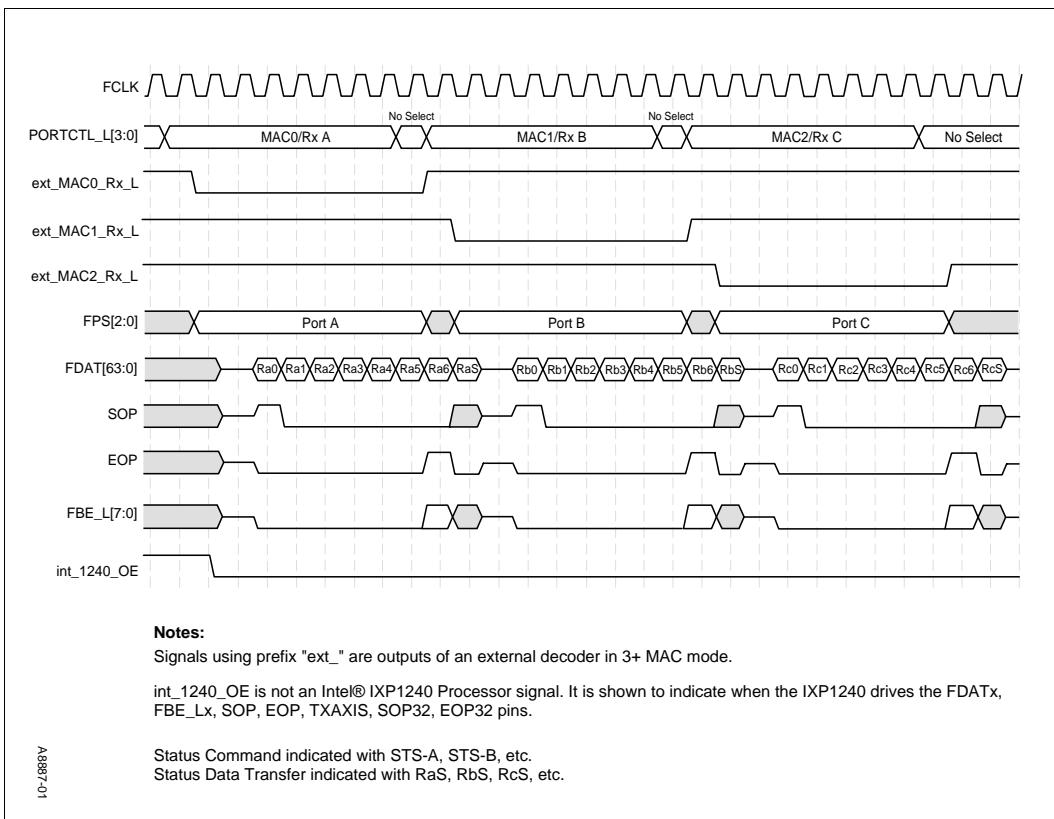

**Figure 31. 64-Bit Bidirectional IX Bus Timing - Consecutive Receives, EOP on 8th Data Return with Status**

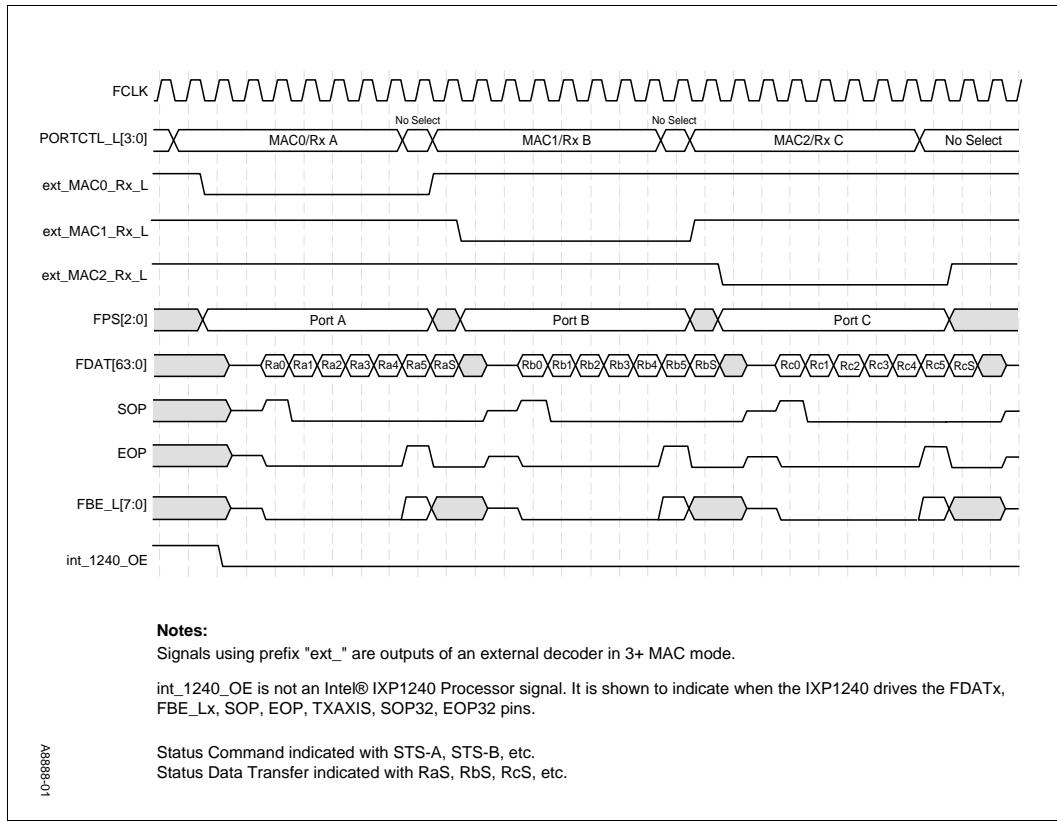

**Figure 32. 64-Bit Bidirectional IX Bus Timing - Consecutive Receives, EOP on 7th Data Return with Status**

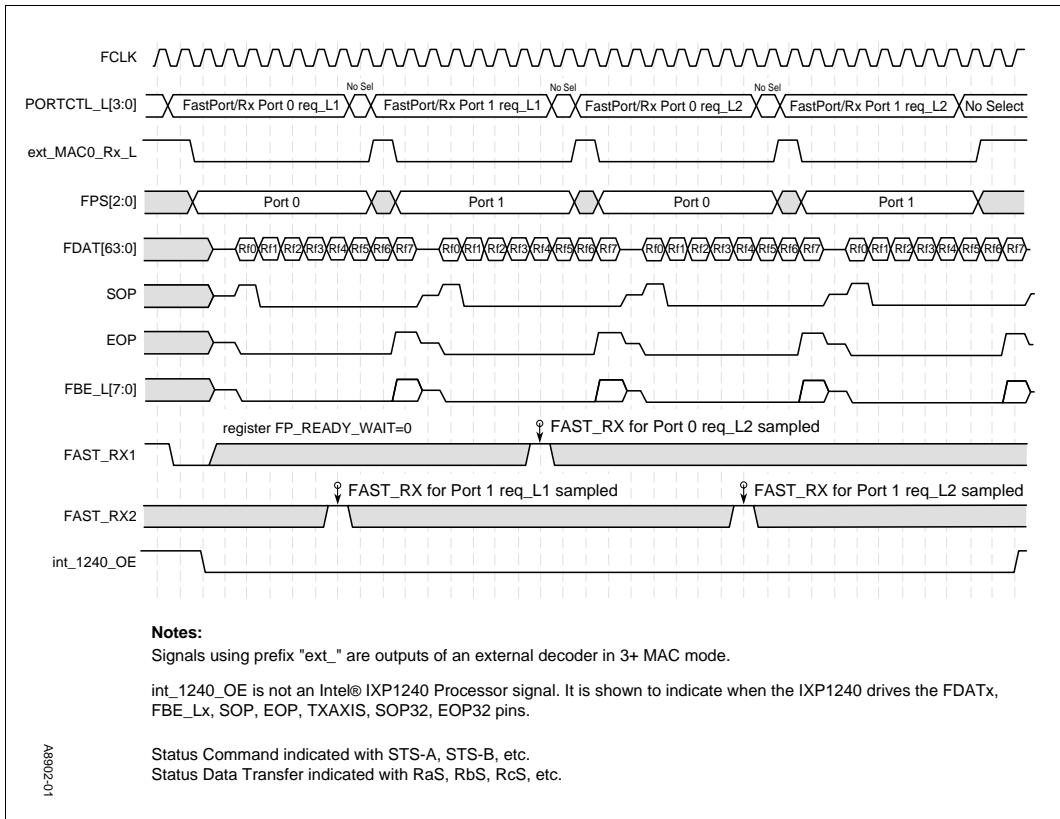

**Figure 52. 64-Bit Bidirectional IX Bus Timing - Consecutive FastPort Receives, Same Port, No EOP, FP\_READY\_WAIT=Don't Care**

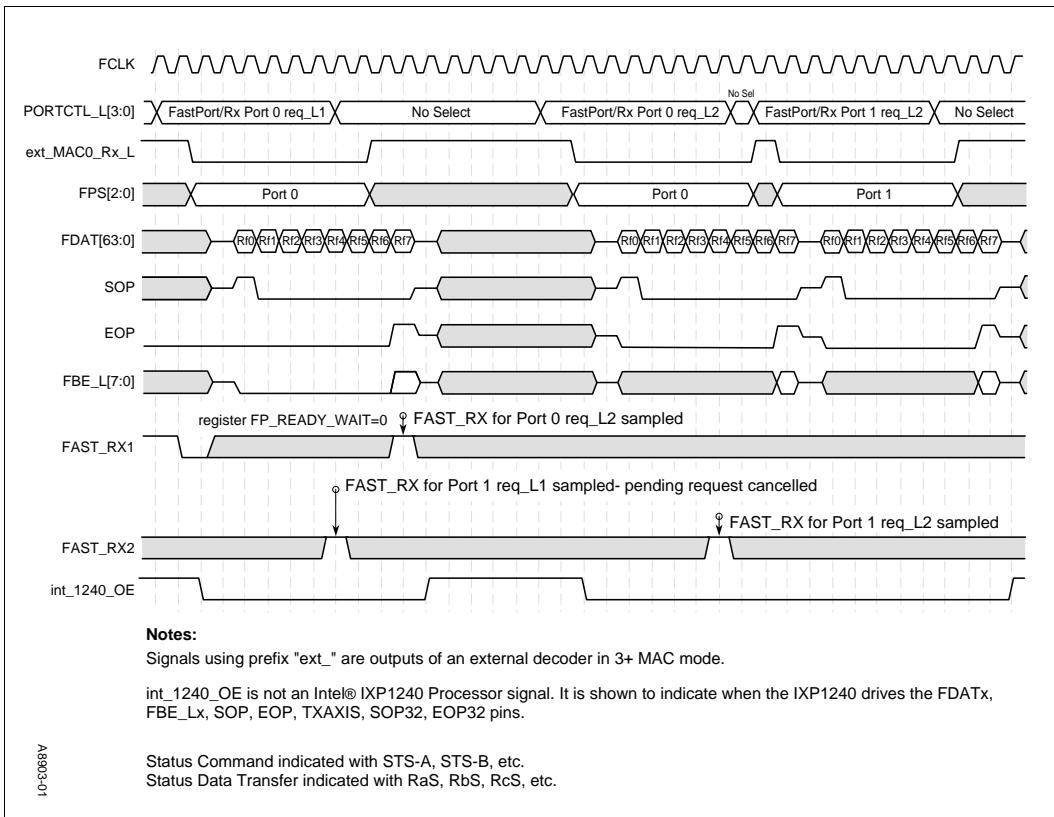

**Figure 53. 64-Bit Bidirectional IX Bus Timing - Consecutive FastPort Receives, Different Ports, EOP, No Status, FP\_READY\_WAIT=0**

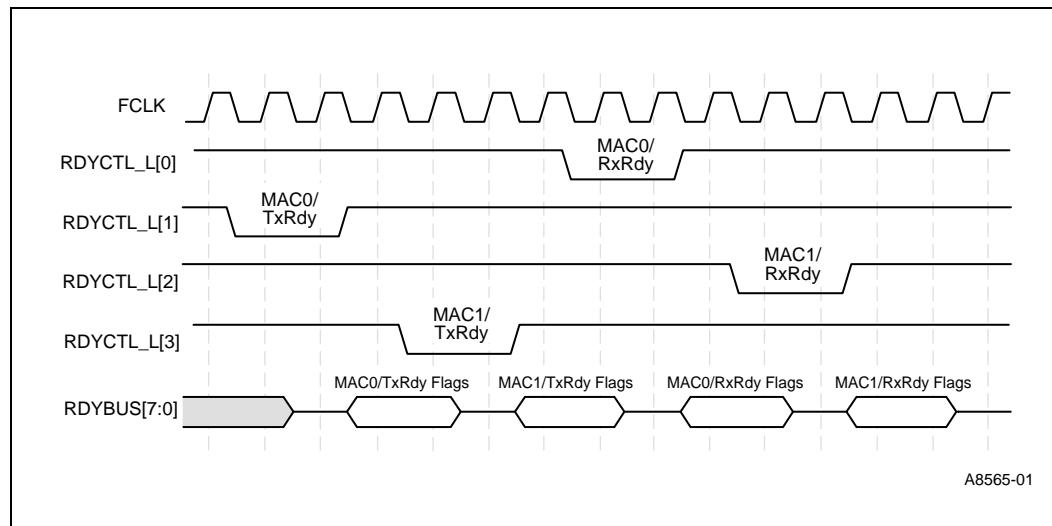

**Figure 54. 64-Bit Bidirectional IX Bus Timing - Consecutive FastPort Receives, Different Ports, EOP, No Status, FP\_READY\_WAIT=0, Cancelled Request**

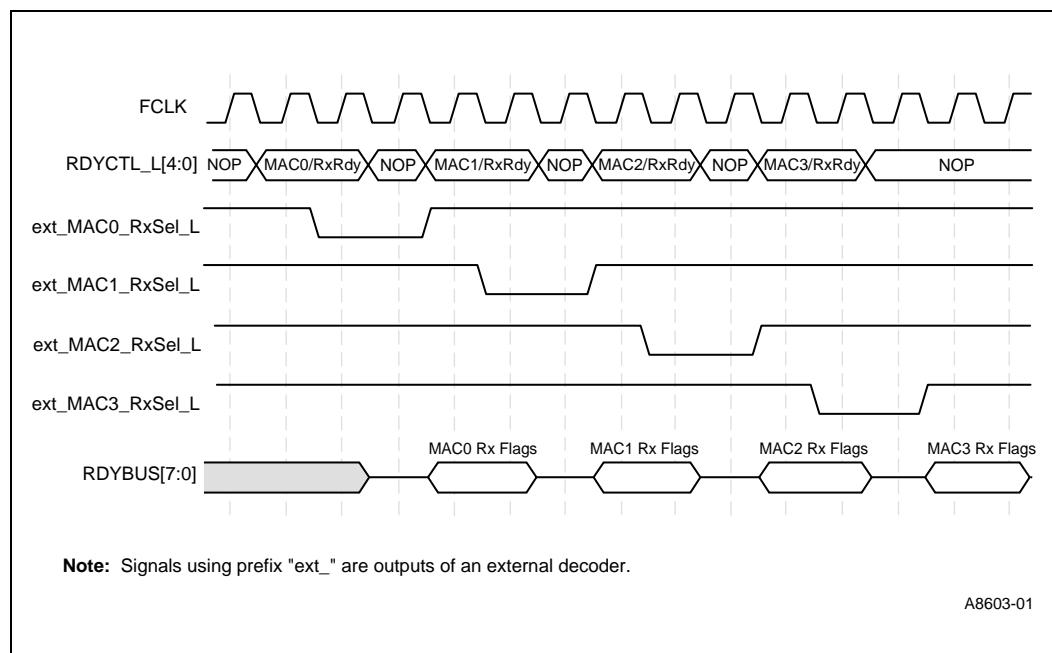

#### 4.3.7.4 RDYBus

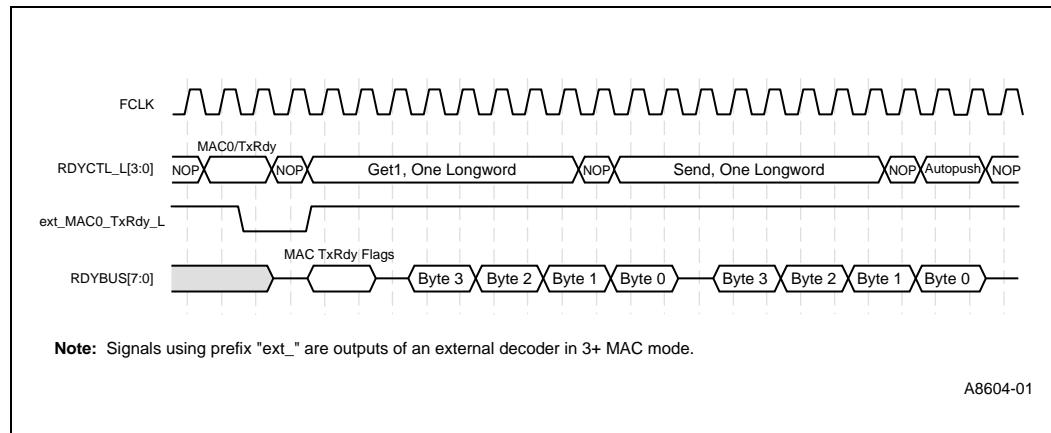

**Figure 55. Consecutive Fetch Ready Flags, 1-2 MAC Mode (with No External Registered Decoder) - RDYBUS\_TEMPLATE\_CTL[10]=1**

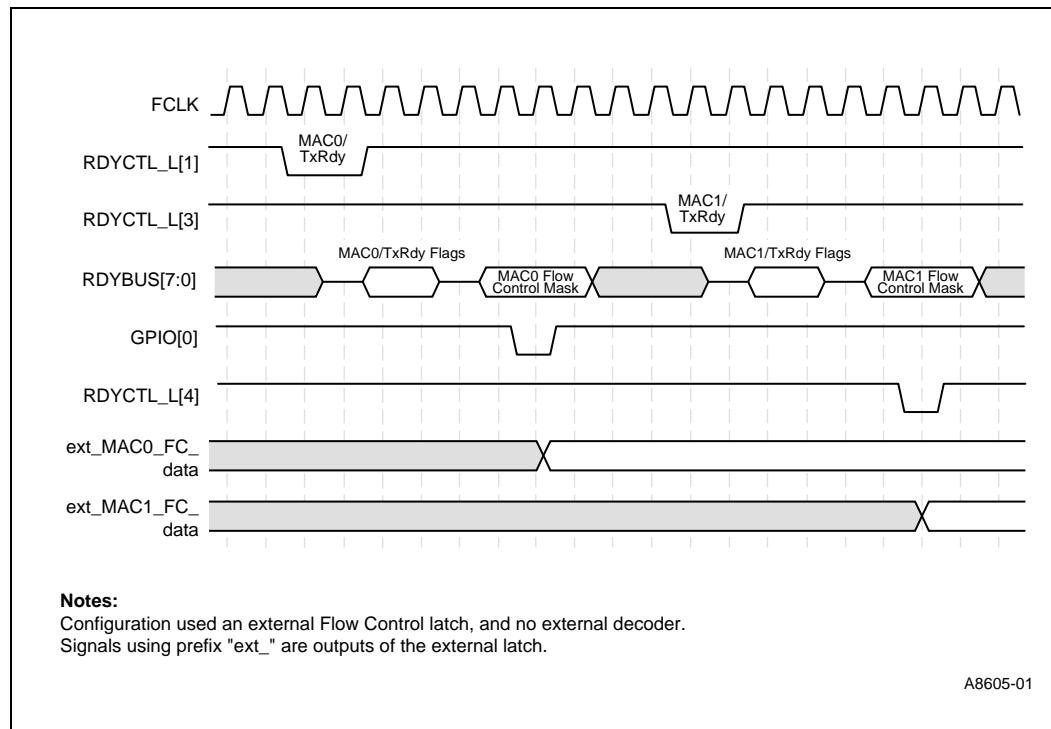

**Figure 56. Consecutive Fetch Ready Flags, 3+ MAC Mode (with External Decoder) - RDYBUS\_TEMPLATE\_CTL[10]=0**

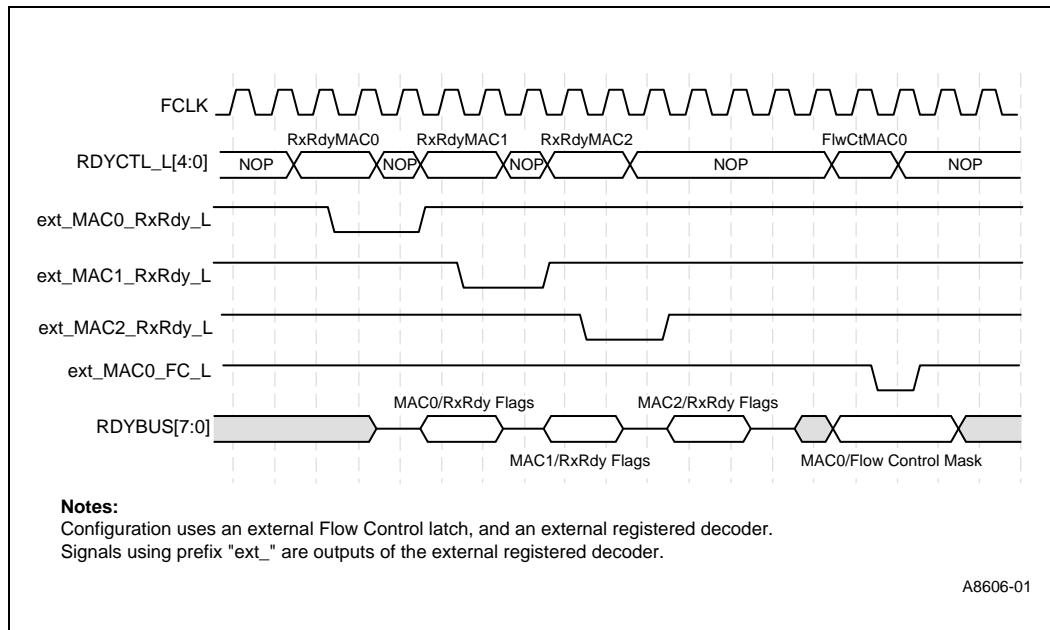

**Figure 57. Fetch Ready Flags, Get/Send Commands, 3+ MAC Mode (with External Registered Decoder) - RDYBUS\_TEMPLATE\_CTL[10]=0**

**Figure 58. Ready Bus Control Timing, Fetch Ready Flags - Flow Control - Fetch Ready Flags, 1-2 MAC Mode (with No External Registered Decoder) - RDYBUS\_TEMPLATE\_CTL[10]=1**

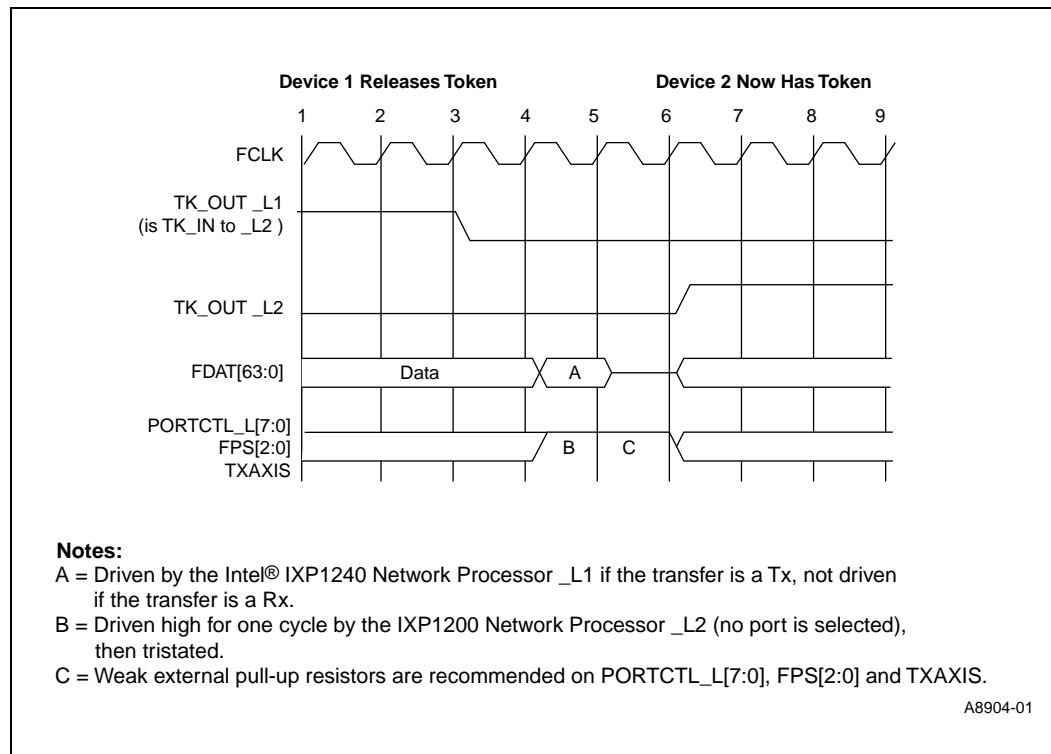

**Figure 59. Ready Bus Control Timing, Fetch Ready Flags - Flow Control - Fetch Ready Flags, 3+ MAC Mode (with External Registered Decoder) - RDYBUS\_TEMPLATE\_CTL[10]=0**

### 4.3.7.5 TK\_IN/TK\_OUT

The following timing diagrams show the transition from one IX Bus owner to another. Note that prior to giving up the bus, the PORTCTL[4:0] signals are driven high which will not select any ports. Then the signal is tri-stated and must be held up with pullup resistors.

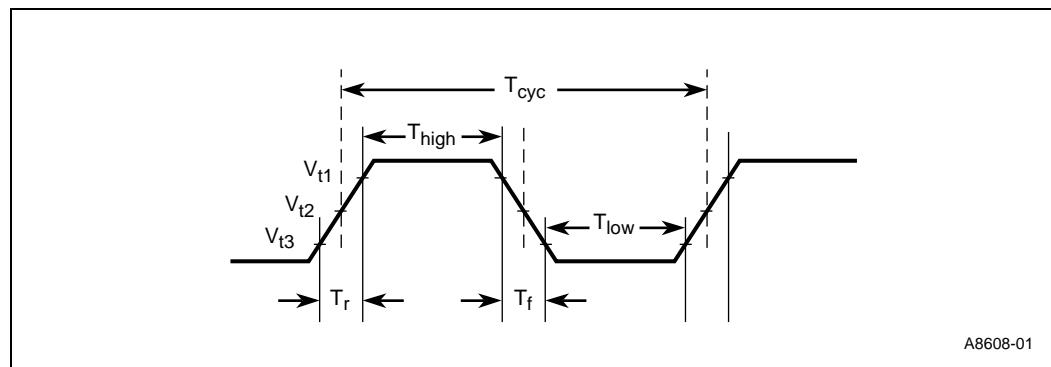

**Figure 60. IX Bus Ownership Passing**

### 4.3.8 SRAM Interface

#### 4.3.8.1 SRAM SCLK Signal AC Parameter Measurements

**Figure 61. SRAM SCLK Signal AC Parameter Measurements**

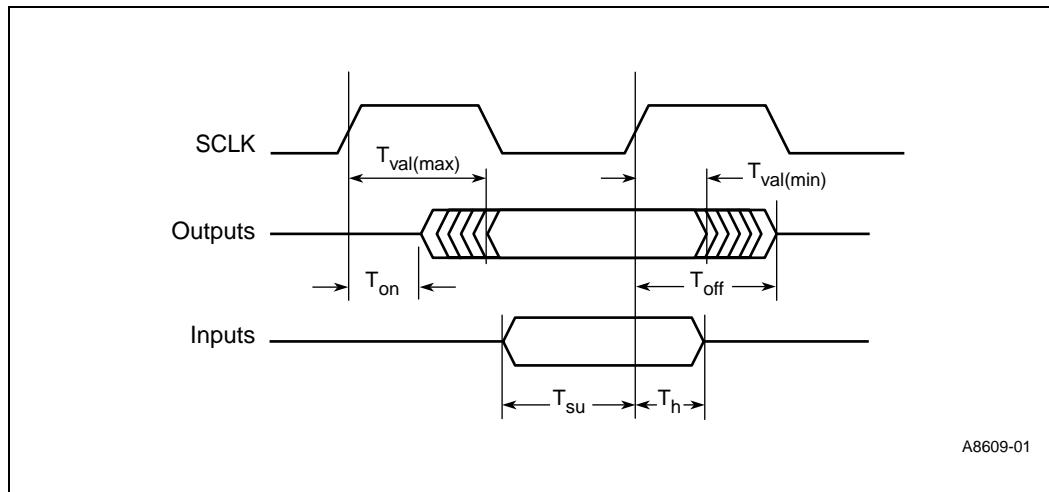

$$\begin{aligned} V_{t1} &= 0.5 * V_{DDX} \\ V_{t2} &= 0.4 * V_{DDX} \\ V_{t3} &= 0.3 * V_{DDX} \end{aligned}$$

**Table 47. SRAM SCLK Signal AC Parameter Measurements**

Symbol	Parameter	Minimum (IXP1240 Core Speed)			Maximum (IXP1240 Core Speed)			Unit
		166 MHz	200 MHz	232 MHz	166 MHz	200 MHz	232 MHz	
Freq	Clock frequency	—	—	—	83	100	116	MHz
T <sub>cyc</sub>	Cycle time	12	10	8.62	—	—	—	ns
T <sub>high</sub>	Clock high time	4.02	4	3.3	—	—	—	ns
T <sub>low</sub>	Clock low time	4.02	4	3.3	—	—	—	ns
T <sub>r</sub> , T <sub>f</sub>	SCLK rise/fall time	0.29	0.25	0.21	1.16	1	0.83	ns

#### 4.3.8.2 SRAM Bus Signal Timing

**Figure 62. SRAM Bus Signal Timing**

**Table 48. SRAM Bus Signal Timing<sup>1,2</sup>**

Symbol	Parameter	Minimum (IXP1240 Core Speed)			Maximum (IXP1240 Core Speed)			Unit
		166 MHz	200 MHz	232 MHz	166 MHz	200 MHz	232 MHz	
$T_{val}$	Clock to data output valid delay <sup>3,4</sup>	1.0	1.0	0.5	5.0	4.5	3.35	ns
$T_{ctl}$	Clock to control outputs valid delay <sup>3,4</sup>	1.25	1.0	0.5	5.0	4.5	3.05	ns
$T_{suf}$	Data input setup time before NA/SACLK for Flowthru SRAM	2	2	2	---	---	---	ns
$T_{sup}$	Data input setup time before SCLK for Pipelined SRAM <sup>5</sup>	5.5	5.0	3.10	---	---	---	ns
$T_{hf}$	Input signal hold time from NA/SACLK for Flowthru SRAM	1	1	1	---	---	---	ns
$T_{hp}$	Input signal hold time from SCLK for Pipelined SRAM	1	1	0.75	---	---	---	ns
$T_{on}^6$	Float-to-active delay from clock	1	1	1	---	---	---	ns
$T_{off}^6$	Active-to-float delay from clock	---	---	---	3	3	3	ns

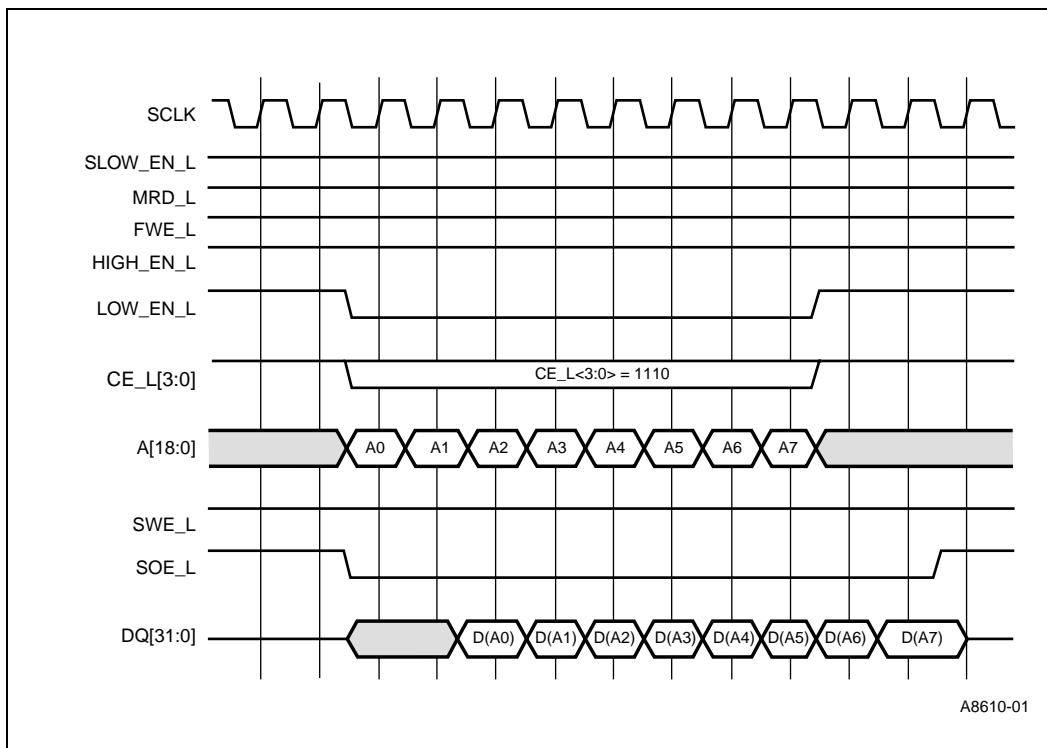

1. Timing parameters assume that the system uses a zero delay clock buffer for SCLK before it is distributed to SRAM.
2. When used as a rdy input, HIGH\_EN\_L is asynchronous and can change anywhere relative to SCLK.
3. Capacitive loading effects on signal lines are shown in Table 49.
4.  $T_{val(min)}$  and 166 MHz and 200 MHz  $T_{ctl(min)}$  parameters are tested under 0 pF load best case conditions ( $Vdd=2.1$ ,  $Vddx=3.6$ , Temp=0 degrees C) at 1.15 nsec with an uncertainty of 0.25 nsec. The parameter specified is guaranteed by design in a minimally configured system environment.
5. Timings are what the tester must measure. Add 0.25 nsec to these numbers to obtain system AC parameter. This additional 0.25 nsec is needed to allow for SRAM drive derating.
6. Not tested. Guaranteed by design.

**Table 49. Signal Delay Deratings for  $T_{val}$  and  $T_{ctl}$** 

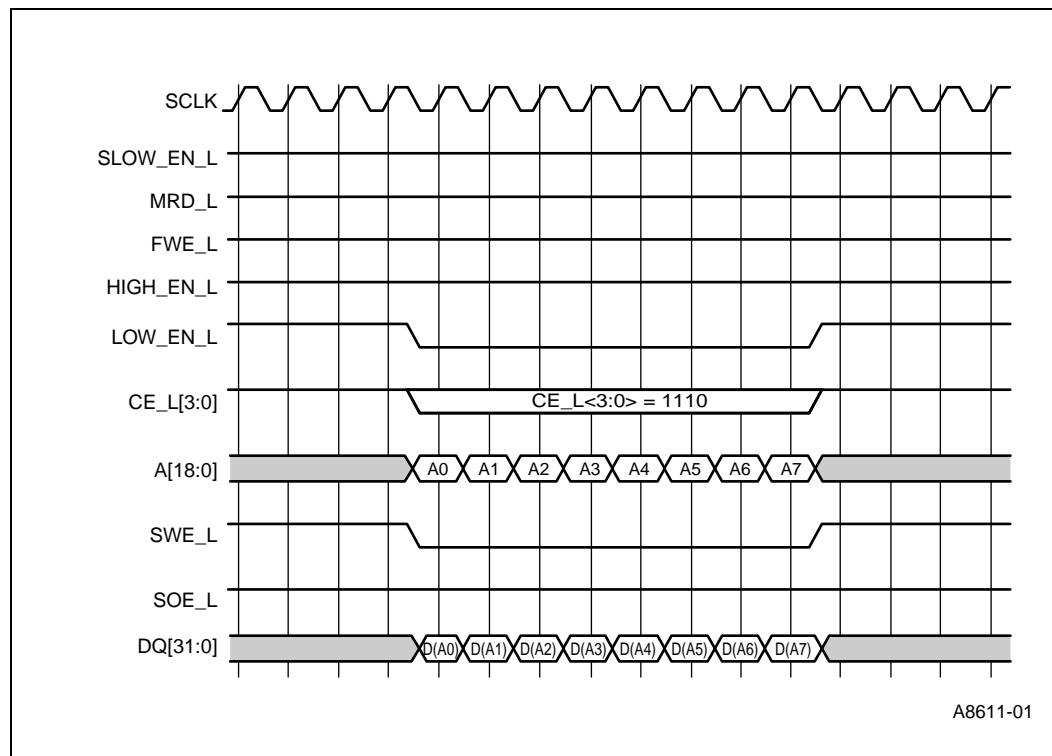

Signal	Maximum Derating (ns/pF) (IX Bus Speed)			Minimum Derating (ns/pF) (IX Bus Speed)		
	83 MHz	100 MHz	116 MHz	83 MHz	100 MHz	116 MHz
SCLK	0.053	—	—	0.025	—	—

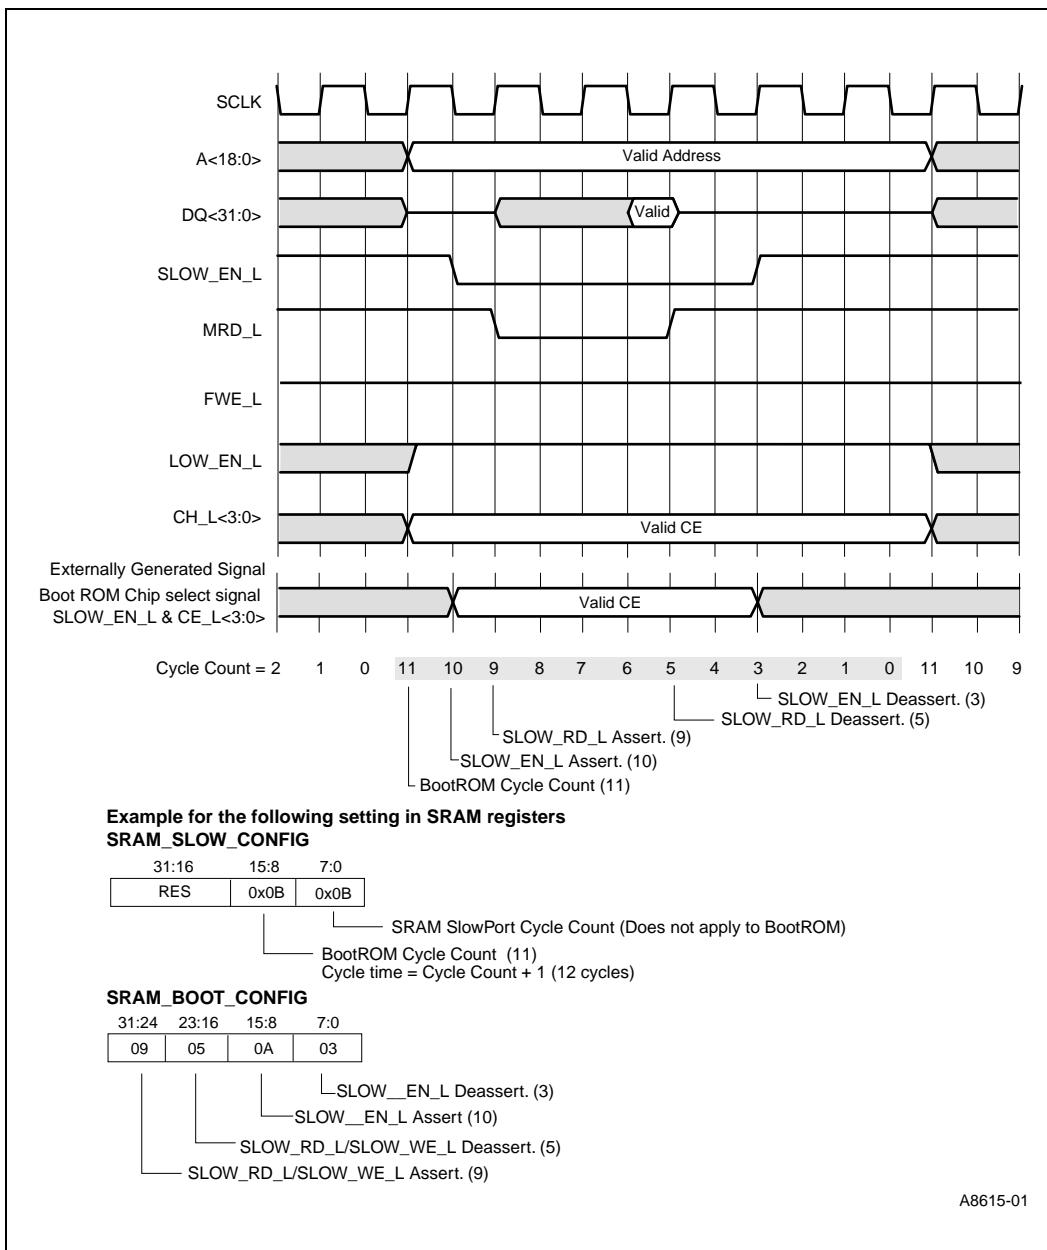

**Figure 67. Flowthrough SRAM Read Burst of Eight Longwords**

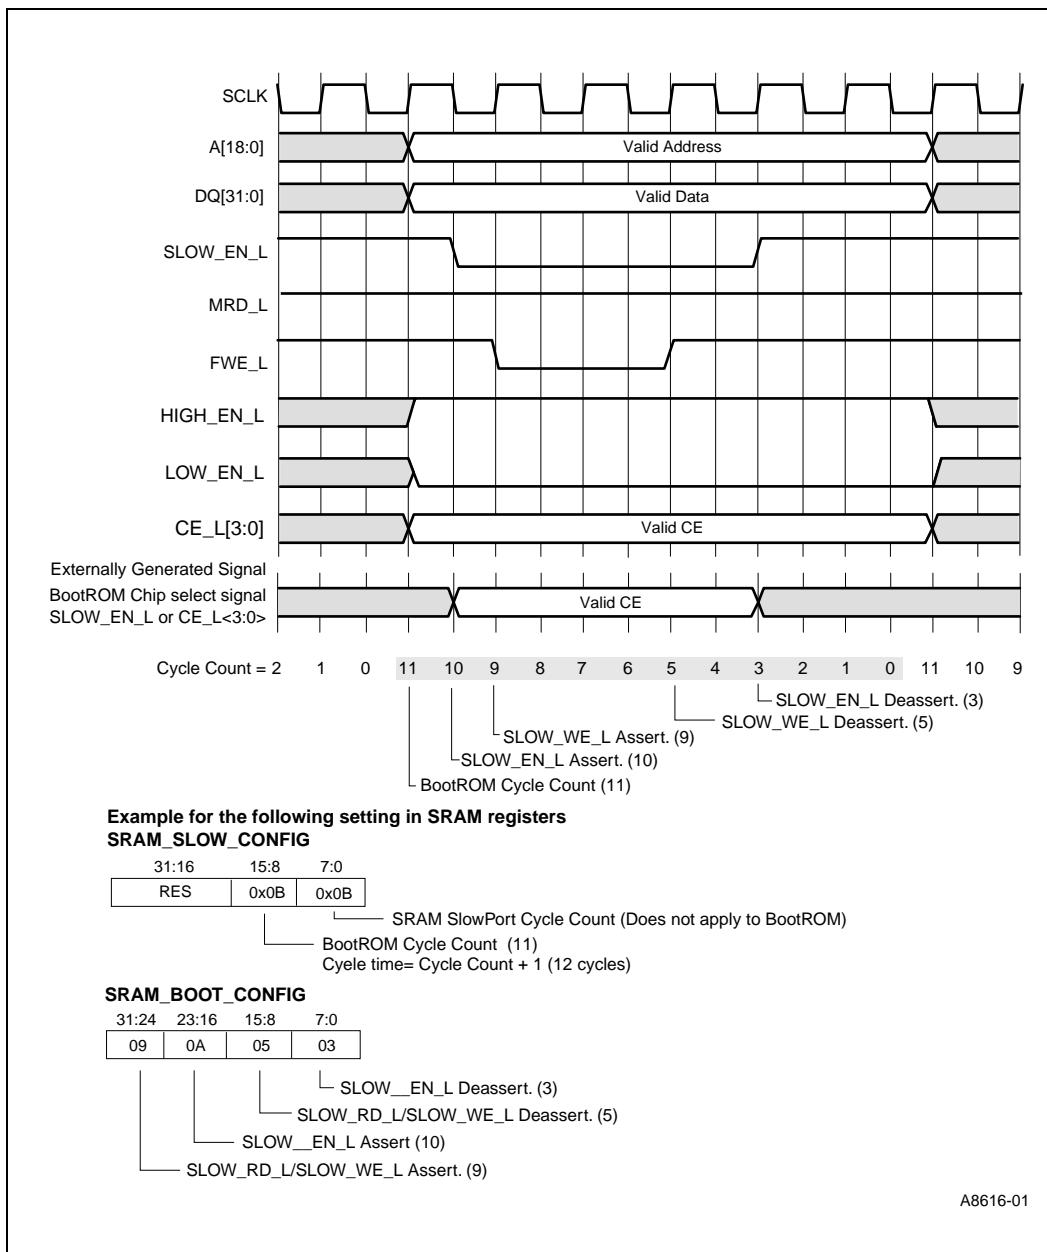

#### 4.3.8.4 SRAM Bus - BootROM and SlowPort Timings

Timing for the BootROM and SlowPort areas are programmable through the SRAM configuration registers described in the *IXP1200 Network Processor Family Microcode Programmer's Reference Manual*. The designer should refer to this manual to understand restrictions in selecting timing values. Each timing illustration shows the appropriate register settings to generate the timing shown.

### 4.3.9 SDRAM Interface

#### 4.3.9.1 SDCLK AC Parameter Measurements

**Figure 75. SDCLK AC Timing Diagram**

$V_{t1} = 0.5 \times V_{DDX}$   
 $V_{t2} = 0.4 \times V_{DDX}$   
 $V_{t3} = 0.3 \times V_{DDX}$

**Table 50. SDCLK AC Parameter Measurements**

Symbol	Parameter	Minimum (IXP1240 Core Speed)			Maximum (IXP1240 Core Speed)			Unit
		166 MHz	200 MHz	232 MHz	166 MHz	200 MHz	232 MHz	
Freq	Clock frequency	—	—	—	83	100	116	MHz
T <sub>cyc</sub>	Cycle time	12	10	8.62	—	—	—	ns
T <sub>high</sub>	Clock high time	4.02	4	3.3	—	—	—	ns
T <sub>low</sub>	Clock low time	4.02	4	3.3	—	—	—	ns
T <sub>r</sub> , T <sub>f</sub>	SDCLK rise/fall time	0.29	0.25	0.21	1.16	1	0.83	ns

#### 4.3.9.2 SDRAM Bus Signal Timing

Figure 76. SDRAM Bus Signal Timing

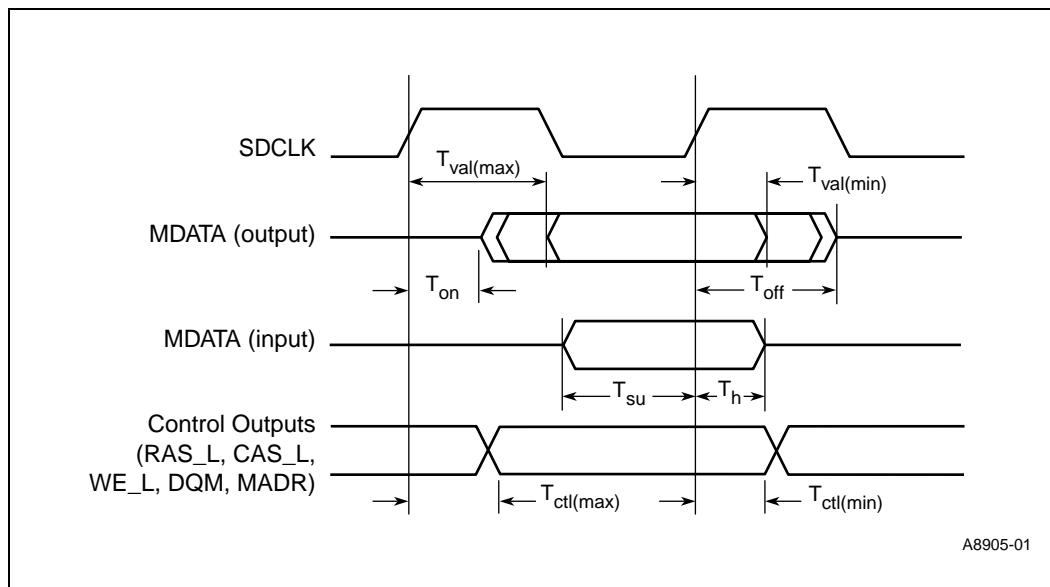

Table 51. SDRAM Bus Signal Timing Parameters<sup>1</sup>

Symbol	Parameter	Minimum (IXP1240 Core Speed)			Maximum (IXP1240 Core Speed)			Unit
		166 MHz	200 MHz	232 MHz	166 MHz	200 MHz	232 MHz	
$T_{val}$	Clock to data output valid delay <sup>2,3</sup>	1.25	1.0	0.5	4.5	4.0	3.3	ns
$T_{ctl}$	SDCLK to control output valid delay <sup>2,3</sup>	1.25	1.0	0.5	4.5	4.0	2.90	ns
$T_{su}$	Data input setup time before SDCLK <sup>4</sup>	4.25	3.70	3.70	---	---	---	ns
$T_h$	Data input hold time from SDCLK	1	1	0.75	---	---	---	ns
$T_{on}^5$	Float to data driven delay from SDCLK	1.25	1	0.75	---	---	---	ns
$T_{off}^5$	Data driven to float delay from SDCLK	---	---	---	3	3	3	ns

1. Timing parameters assume that the system uses a zero delay clock buffer for SDCLK before it is distributed to SDRAM.

2. Capacitive loading effects on signal lines are shown in Table 52.

3.  $T_{val(min)}$  and 166 MHz and 200 MHz  $T_{ctl(min)}$  parameters are tested under 0 pF load best case conditions ( $V_{dd}=2.1$ ,  $V_{ddx}=3.6$ ,  $\text{Temp}=0$  degrees C) at 1.15 nsec with an uncertainty of 0.25 nsec. The parameter specified is guaranteed by design in a minimally configured system environment.

4. Unlike the SRAM setup timing parameter  $T_{sup}$ , the  $T_{su}$  timings are both what the tester must measure and what the SDRAM parts will deliver. Increased performance on the SDRAM bus occurs because the data pins only drive one load.

5. Not tested. Guaranteed by design.

**Table 52. Signal Delay Deratings for T<sub>val</sub> and T<sub>ctl</sub>**

Signal	Maximum Derating (ns/pF) (IX Bus Speed)			Minimum Derating (ns/pF) (IX Bus Speed)		
	83 MHz	100 MHz	116 MHz	83 MHz	100 MHz	116 MHz

MADR[14:0]	0.065	0.06	0.031	0.03	0.025	0.015
MDATA[63:0]	0.095	0.09	0.035	0.03	0.025	0.015

### 4.3.9.3 SDRAM Signal Protocol

This section describes the SDRAM timing parameters referenced in the SDRAM timing diagrams that follow. This nomenclature is consistent with most JEDEC standard SDRAM devices.

#### tRP

tRP is the minimum number of cycles after a precharge cycle that a bank may be opened (or "RASd"). The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tRP Precharge Time. Also referred to as "PRECHARGE command period" in SDRAM datasheets.

#### tRASmin

tRASmin is the minimum number of cycles that a bank must be open before it can be closed using a precharge command. The maximum time that a bank may be open, tRASmax, is not checked, because the IXP1240 SDRAM Controller methodology is to close all banks after the usage is complete. The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tRASmin Active Command Period. Also referred to as "ACTIVE to PRECHARGE command period" in SDRAM datasheets.

#### tRCD

tRCD is the number of cycles between the bank opening (or "RAS") and any read or write command (or "CAS"). The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tRCD RAS to CAS Delay. Also referred to as "ACTIVE to READ or WRITE delay" in SDRAM datasheets.

#### tRRD

tRRD is the number of cycles between successive bank openings, or RAS cycles. The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tRRD Bank to Bank Delay Time. Also referred to as "ACTIVE bank A to ACTIVE bank B command" in SDRAM datasheets.

#### tRC

tRC is the SDRAM bank cycle time, indicating that the minimum time that a command may be active. For most cases, this is the sum of tRP and tRASmin, although there are some SDRAM data sheets where the absolute time for tRC (in ns) is not equal to the sum (in ns) of tRP and tRASmin. In these cases, typically when rounding up to an even number of clock cycles, they are equivalent. Since the SDRAM Controller CSRs are programmed with a number of clock cycles, these SDRAMs timing values would appear consistent. tRC is used only to specify the number of cycles between Refresh cycles during initialization of the SDRAM parts. It is possible to eliminate it

altogether, and simply have this time be the sum of tRP and tRASmin, as discussed above. The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tRC Bank Cycle Time. Also referred to as "ACTIVE to ACTIVE command period" in SDRAM datasheets.

#### **tDPL**

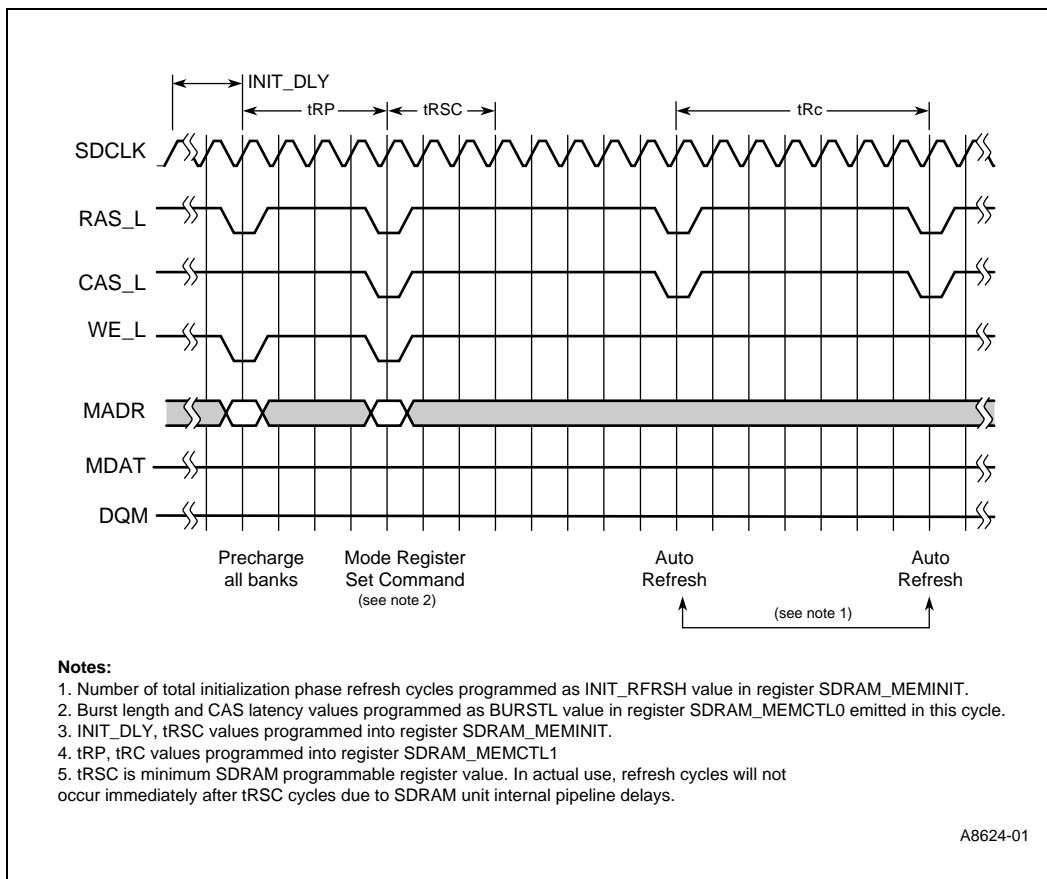

tDPL is the number of cycles after the final data write that a precharge may occur. tDPL = 1 indicates that a precharge may occur on the next cycle. The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tDPL Data In to Precharge Time. Also referred to as "Data-in to PRECHARGE command time" in SDRAM datasheets.

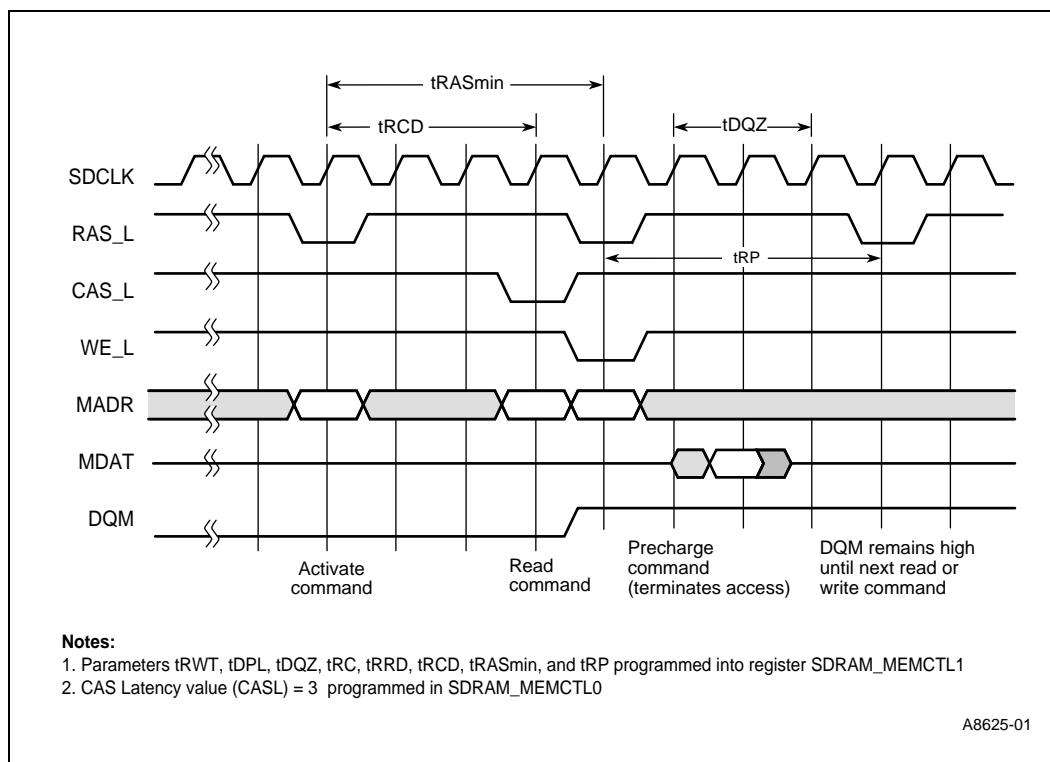

#### **tDQZ**

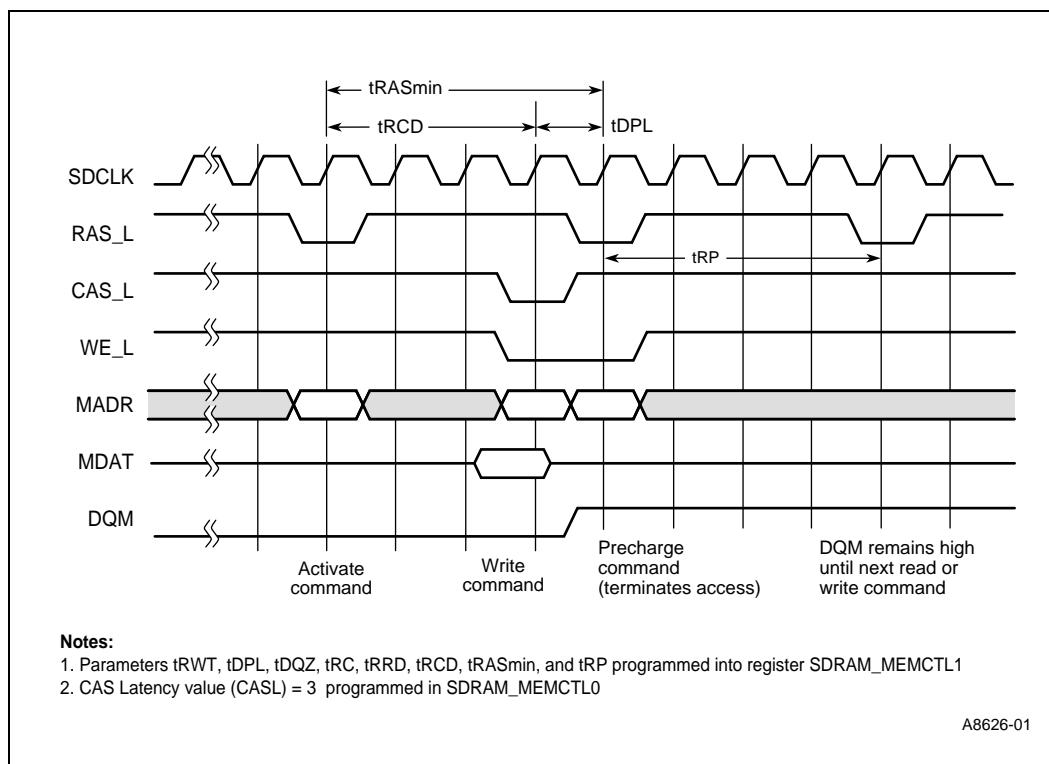

tDQZ indicates the number of cycles of latency after DQM is seen that the SDRAMs will go into a high-impedance state. For tDQZ = 2, DQM get sampled on the first edge, the SDRAMs get off the bus on the next edge, and the bus may be driven on the third edge. The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tDQZ DQM Data Out Disable Latency. Also referred to as "DQM to data high-impedance during READS" in SDRAM datasheets.

#### **tRWT**

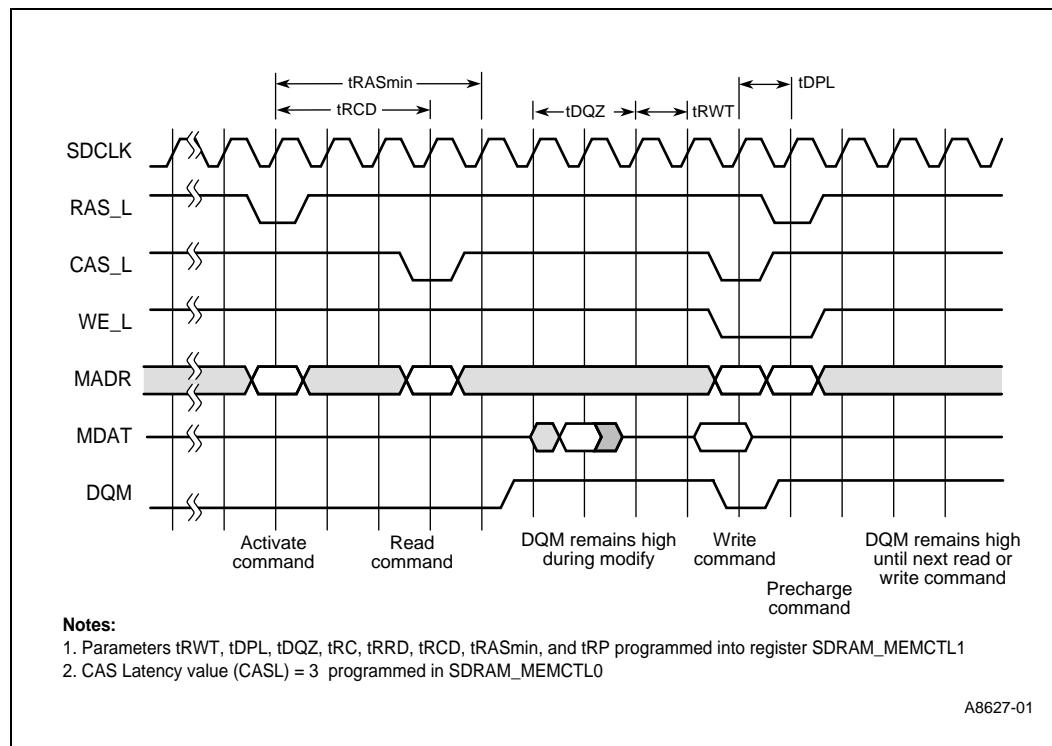

Note that for most designs, there may be a requirement to add one or more dead cycles after the SDRAMs get off the bus to avoid possible bus contention on the DQM bus. This will be a function of the design itself (i.e., component placement, bus loading, the SDRAMs used and tHZ, the time that it takes for the SDRAM to go to a high-Z state) and the frequency at which the SDRAM interface is running. If extra dead cycles are necessary on a write following read bus turnaround, the tRWT should be programmed to a non-zero value. If tRWT is one, then one dead cycle will be added following the completion of a read prior to a write access taking place. The *IXP1200 Network Processor Family Microcode Programmer's Reference Manual* refers to this as the tRWT Read/write Turnaround Time. Not explicitly specified in SDRAM data sheets, but is a function of memory system design, loading. Most PC100 type SDRAM devices allow a zero-delay read-write turnaround. However, tHZmax for PC100 devices is 5.4ns (CASL=2) or 7 ns (CASL=3) and tON for the IXP1240 is 1 ns, so a 1 clock tRWT would be required to avoid bus contention.

## 4.4

### Asynchronous Signal Timing Descriptions

**RESET\_IN\_L** Must remain asserted for 150 ms after VDD and VDDX are stable to properly reset the IXP1240.

**RESET\_OUT\_L** Is asserted for all types of reset (hard, watchdog, and software) and appears on the pin asynchronously to all clocks.

**GPIO[3:0]** Are read and written under software control. When writing a value to these pins, the pins transition approximately 20 ns after the write is performed. When reading these pins, the signal is first synchronized to the internal clock and must be valid for at least 20 ns before it is visible to a processor read.

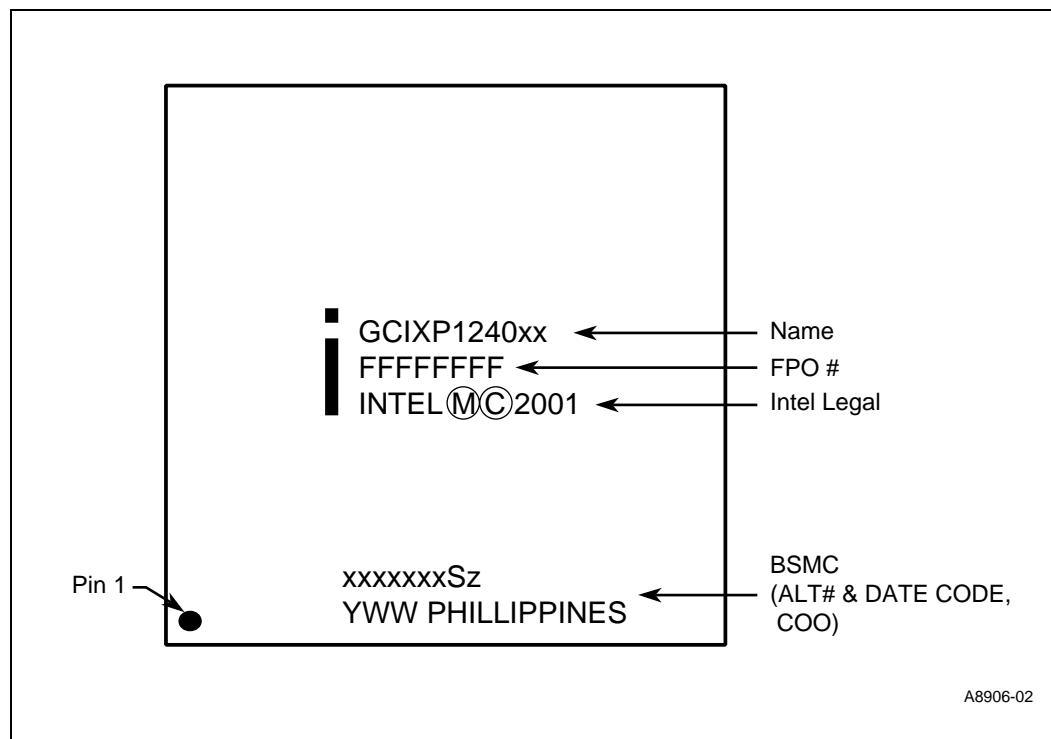

**TXD, RXD** Are asynchronous relative to any device outside the IXP1240.

## 5.0 Mechanical Specifications

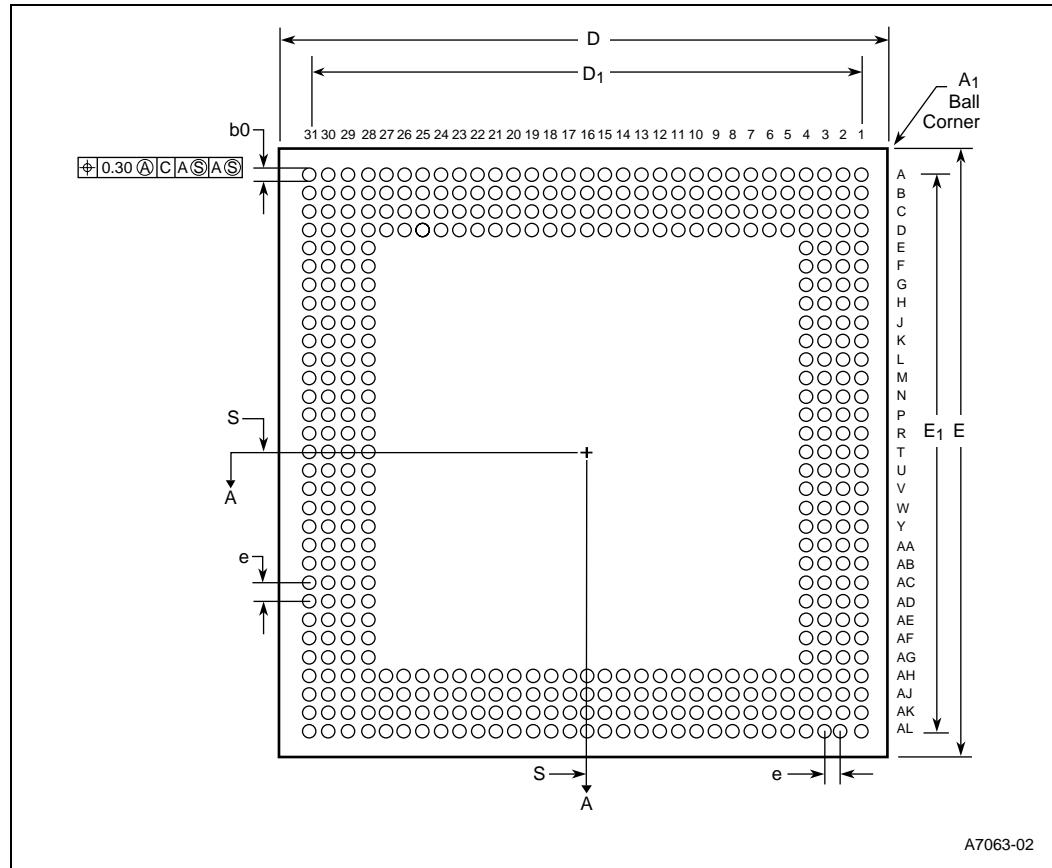

### 5.1 Package Dimensions

The IXP1240 is contained in a 432-HL-PBGA package, as shown in the following illustrations.

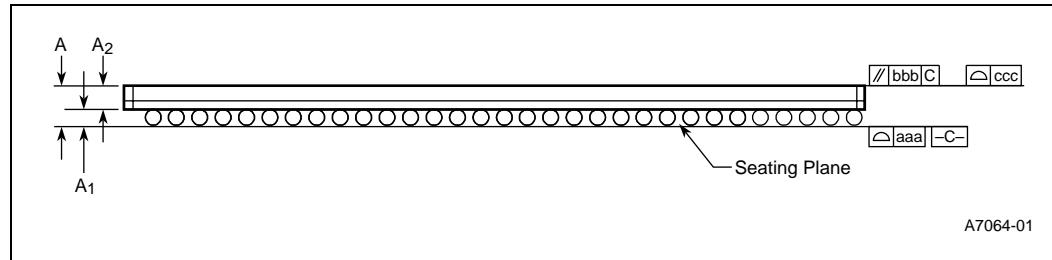

**Figure 81. IXP1240 Part Marking**

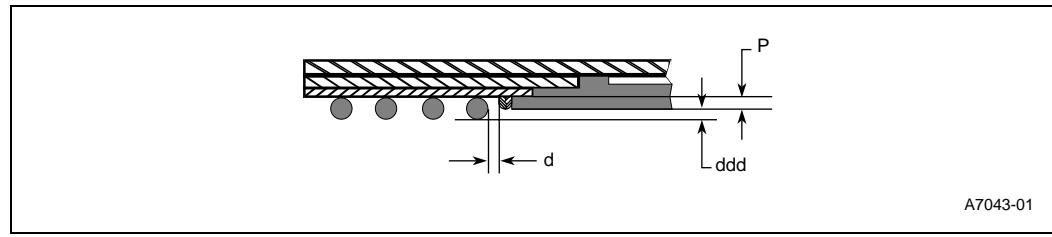

**Figure 82. 432-Pin HL-PBGA Package - Bottom View**

**Figure 83. IXP1240 Side View**

**Figure 84. IXP1240 A-A Section View**

## 5.2 IXP1240 Package Dimensions (mm)

**Table 53. IXP1240 Package Dimensions (mm)**

Symbol	Definition	Minimum	Nominal	Maximum
A	Overall thickness	1.41	1.54	1.67
A <sub>1</sub>	Ball height	0.56	0.63	0.70
A <sub>2</sub>	Body thickness	0.85	0.91	0.97
D	Body size	39.90	40.00	40.10
D <sub>1</sub>	Ball footprint	38.00	38.10	38.20
E	Body size	39.90	40.00	40.10
E <sub>1</sub>	Ball footprint	38.00	38.10	38.20
b	Ball diameter	0.60	0.75	0.90
aaa	Coplanarity	--	--	0.20
bbb	Parallel	--	--	0.15
ccc	Top flatness	--	--	0.20
ddd [8]	Seating plane clearance	0.15	0.33	0.50
P	Encapsulation height	0.20	0.30	0.35
S	Solder ball placement	--	--	0.00
M, N	Ball matrix	--	31 x 31	--
M1[7]	Number of rows deep	--	4	--
d	Minimum distance, encap to balls	--	0.6	--
e	Ball pitch	--	1.27	--

**NOTES:**

1. All dimensions and tolerances conform to ANSI Y1.45M-1982.
2. Dimension "b" is measured at the maximum solder ball diameter parallel to primary datum "c".
3. Primary datum "c" and seating plane are defined by the spherical crowns of the solder balls.
4. Pin A1 I.D. marked by ink.
5. Shape at corner, single form.
6. All dimensions are in millimeters.
7. Number of rows in from edge to center.
8. Height from ball seating plane to plane of encapsulant.
9. S is measured with respect to -A- and -B- and defines the position of the center solder ball in the outer row.  
When there is an odd number of solder balls in the outer row, S=0.000; when there is an even number of solder balls in the outer row, the value S=e/2. S can be either 0.000 or e/2 for each variation.
10. The dimension from the outer edge of the resin dam to the edge of the innermost row of the solder ball pads is to be a minimum of 0.50 mm.
