

FEATURES

- 4-wire touch screen interface
- LCD noise reduction feature (STOPACQ pin)
- Automatic conversion sequencer and timer
- User-programmable conversion parameters
- On-chip temperature sensor: -40°C to $+85^{\circ}\text{C}$
- On-chip 2.5 V reference
- On-chip 8-bit DAC
- 3 auxiliary analog inputs
- 1 dedicated and 3 optional GPIOs
- 2 direct battery measurement channels (0.5 V to 5 V)
- 3 interrupt outputs
- Touch-pressure measurement
- Wake up on touch function
- Specified throughput rate of 125 kSPS
- Single supply, V_{CC} of 2.7 V to 5.25 V
- Separate V_{DRIVE} level for serial interface
- Shutdown mode: 1 μA maximum
- 32-lead, LFCSP, 5 mm \times 5 mm package
- 25-ball, WLCSP, 2.5 mm \times 2.8 mm package

APPLICATIONS

- Personal digital assistants
- Smart hand-held devices
- Touch screen monitors
- Point-of-sale terminals
- Medical devices
- Cell phones
- Pagers

GENERAL DESCRIPTION

The AD7877 is a 12-bit, successive approximation ADC with a synchronous serial interface and low on resistance switches for driving touch screens. The AD7877 operates from a single 2.7 V to 5.25 V power supply (functional operation to 2.2 V), and features throughput rates of 125 kSPS. The AD7877 features direct battery measurement on two inputs, temperature and touch-pressure measurement.

The AD7877 also has an on-board reference of 2.5 V. When not in use, it can be shut down to conserve power. An external reference can also be applied and varied from 1 V to $+V_{CC}$, with an analog input range of 0 V to V_{REF} . The device includes a shutdown mode that reduces its current consumption to less than 1 μA .

Rev. B

FUNCTIONAL BLOCK DIAGRAM

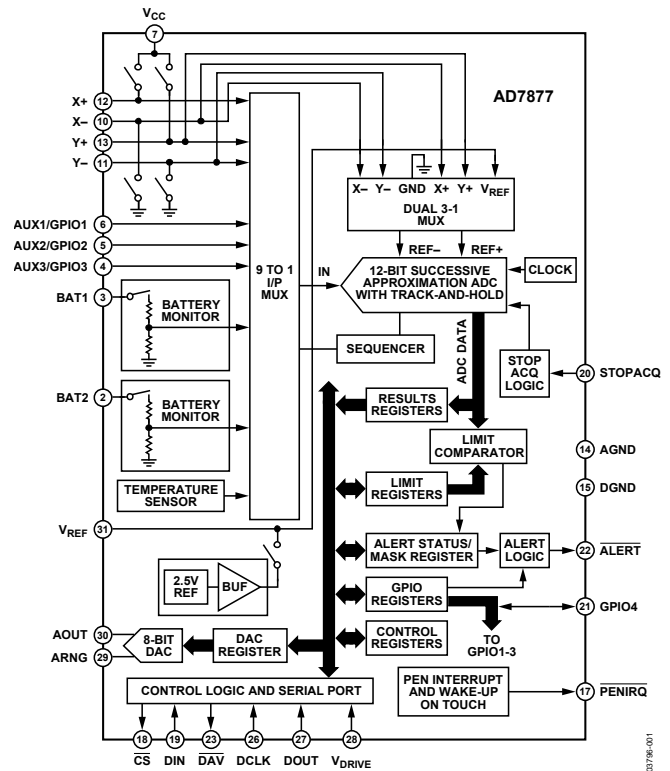

Figure 1.

To reduce the effects of noise from LCDs, the acquisition phase of the on-board ADC is controlled via the STOPACQ pin. User-programmable conversion controls include variable acquisition time and first conversion delay. Up to 16 averages can be taken per conversion. There is also an on-board DAC for LCD back-light or contrast control. The AD7877 runs in either slave or master mode using a conversion sequencer and timer. It is ideal for battery-powered systems such as personal digital assistants with resistive touch screens and other portable equipment.

The part is available in a 32-lead lead frame chip scale package (LFCSP), and a 25-ball wafer level chip scale package (WLCSP).

| Shutdown Mode | | | 1 | μA | |

¹ See the Terminology section.

² Difference between Temp0 and Temp1 measurement. No calibration necessary.

³ Temperature drift is $-2.1\text{ mV}/^\circ\text{C}$.

⁴ Sample tested @ 25°C to ensure compliance.

TIMING SPECIFICATIONS

$T_A = T_{MIN}$ to T_{MAX} , unless otherwise noted, $V_{CC} = 2.7$ V to 5.25 V, $V_{REF} = 2.5$ V. Sample tested at 25°C to ensure compliance. All input signals are specified with $t_R = t_F = 5$ ns (10% to 90% of V_{CC}) and timed from a voltage level of 1.6 V.

Table 2.

| Parameter | Limit at T_{MIN} , T_{MAX} | Unit | Description |
|--------------|--------------------------------|--------------------|--|
| f_{DCLK}^1 | 10 20 | kHz min MHz max | |
| t_1 | 16 | ns min | \overline{CS} falling edge to first DCLK rising edge |
| t_2 | 20 | ns min | DCLK high pulse width |
| t_3 | 20 | ns min | DCLK low pulse width |
| t_4 | 12 | ns min | DIN setup time |
| t_5 | 12 | ns min | DIN hold time |
| t_6^2 | 16 | ns max | \overline{CS} falling edge to DOUT, three-state disabled |
| t_7^2 | 16 | ns max | DCLK falling edge to DOUT valid |
| t_8^3 | 16 | ns max | \overline{CS} rising edge to DOUT high impedance |
| t_9 | 0 | ns min | \overline{CS} rising edge to DCLK ignored |

¹ Mark/space ratio for the DCLK input is 40/60 to 60/40.

² Measured with the load circuit of Figure 3 and defined as the time required for the output to cross 0.4 V or 2.0 V.

³ t_8 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit shown in Figure 3. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time, t_8 , quoted in the timing characteristics is the true bus relinquish time of the part and is independent of the bus loading.

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 3.

| Parameter | Rating |
|---|-----------------------------------|
| V_{CC} to GND | -0.3 V to +7 V |
| Analog Input Voltage to GND | -0.3 V to $V_{CC} + 0.3$ V |
| Digital Input Voltage to GND | -0.3 V to $V_{CC} + 0.3$ V |
| Digital Output Voltage to GND | -0.3 V to $V_{CC} + 0.3$ V |
| V_{REF} to GND | -0.3 V to $V_{CC} + 0.3$ V |
| Input Current to Any Pin Except Supplies ¹ | 10 mA |
| ESD Rating (IEC 1000-4-2, Air Discharge) | |
| Tablet Pins (X+, X-, Y+, Y-) | 4 kV |
| Other Pins | 2 kV |
| Operating Temperature Range | -40°C to +85°C |
| Storage Temperature Range | -65°C to +150°C |
| Junction Temperature | 150°C |
| LFCSP Package | |
| Power Dissipation | 450 mW |
| θ_{JA} Thermal Impedance | 135.7°C/W |
| IR Reflow Peak Temperature | 220°C |
| Pb-Free Parts Only | 260°C ($\pm 0.5^\circ\text{C}$) |
| Lead Temperature (Soldering 10 sec) | 300°C |

¹ Transient currents of up to 100 mA do not cause SCR latch-up.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

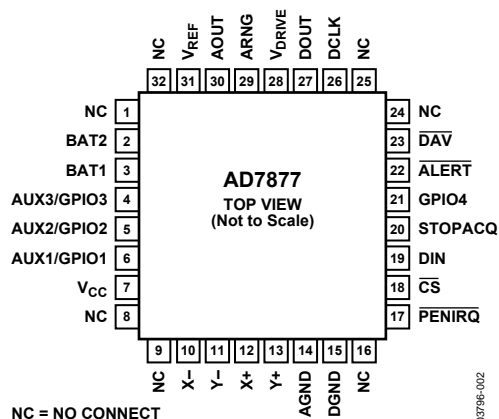

Figure 4. LFCSP Pin Configuration

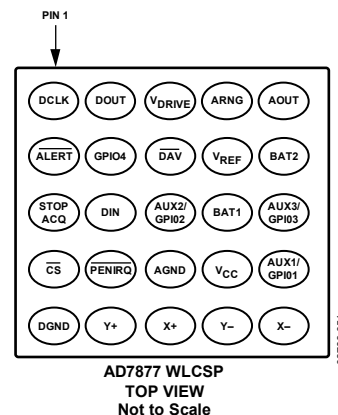

Figure 5. WLCSP Pin Configuration

Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
|-------------------------|----------------------------|--|
| 1, 8, 9, 16, 24, 25, 32 | NC | No Connect. |
| 2 | BAT2 | Battery Monitor Input. ADC Input Channel 7. |
| 3 | BAT1 | Battery Monitor Input. ADC Input Channel 6. |
| 4 | AUX3/GPIO3 | Auxiliary Analog Input. ADC Input Channel 5. Can be reconfigured as GPIO pin. |
| 5 | AUX2/GPIO2 | Auxiliary Analog Input. ADC Input Channel 4. Can be reconfigured as GPIO pin. |
| 6 | AUX1/GPIO1 | Auxiliary Analog Input. ADC Input Channel 3. Can be reconfigured as GPIO pin. |
| 7 | V _{CC} | Power Supply Input. The V _{CC} range for the AD7877 is from 2.2 V to 5.25 V. |
| 10 | X- | Touch Screen Position Input. |
| 11 | Y- | Touch Screen Position Input. ADC Input Channel 2. |
| 12 | X+ | Touch Screen Position Input. ADC Input Channel 0. |
| 13 | Y+ | Touch Screen Position Input. ADC Input Channel 1. |
| 14 | AGND | Analog Ground. Ground reference point for all analog circuitry on the AD7877. All analog input signals and any external reference signal should be referred to this voltage. |
| 15 | DGND | Digital Ground. Ground reference for all digital circuitry on the AD7877. Refer all digital input signals to this voltage. |
| 17 | $\overline{\text{PENIRQ}}$ | Pen Interrupt. Digital active low output (has a 50 k Ω internal pull-up resistor). |
| 18 | $\overline{\text{CS}}$ | Chip Select Input. Active low logic input. This input provides the dual function of initiating conversions on the AD7877 and enabling the serial input/output register. |
| 19 | DIN | SPI [®] Serial Data Input. Data to be written to the AD7877 registers are provided on this input and clocked into the register on the rising edge of DCLK. |
| 20 | STOPACQ | Stop Acquisition Pin. A signal applied to this pin can be monitored by the AD7877, so that acquisition of new data by the ADC is halted while the signal is active. Used to reduce the effect of noise from an LCD screen on the touch screen measurements. |
| 21 | GPIO4 | Dedicated General-Purpose Logic Input/Output Pin. |
| 22 | $\overline{\text{ALERT}}$ | Digital Active Low Output. Interrupt output that goes low if a GPIO data bit is set, or if the AUX1, TEMP1, BAT1, or BAT2 measurements are out of range. |
| 23 | $\overline{\text{DAV}}$ | Data Available Output. Active low logic output. Asserts low when new data is available in the AD7877 results registers. This output is high impedance when $\overline{\text{CS}}$ is high. |
| 26 | DCLK | External Clock Input. Logic input. DCLK provides the serial clock for accessing data from the part. |
| 27 | DOUT | Serial Data Output. Logic output. The conversion result from the AD7877 is provided on this output as a serial data stream. The bits are clocked out on the falling edge of the DCLK input. This output is high impedance when $\overline{\text{CS}}$ is high. |
| 28 | V _{DRIVE} | Logic Power Supply Input. The voltage supplied at this pin determines the operating voltage for the serial interface of the AD7877. |

AD7877

| Pin No. | Mnemonic | Description |
|---------|------------------|--|
| 29 | ARNG | When the DAC is in current output mode, a resistor from ARNG to GND sets the output range. |
| 30 | AOUT | Analog Output Voltage or Current from DAC. |
| 31 | V _{REF} | Reference Output for the AD7877. The internal 2.5 V reference is available on this pin for use external to the device. The reference output must be buffered before it is applied elsewhere in a system. To reduce system noise effects, it is strongly recommended to place a capacitor of 100 nF between the V _{REF} pin and GND. Alternatively, an external reference can be applied to this input. The voltage range for the external reference is 1.0 V to V _{CC} . For the specified performance, it is 2.5 V on the AD7877. |

TYPICAL PERFORMANCE CHARACTERISTICS

$T_A = 25^\circ\text{C}$, $V_{CC} = 2.7\text{ V}$, $V_{REF} = 2.5\text{ V}$, $f_{SAMPLE} = 125\text{ kHz}$, $f_{DCLK} = 16 \times f_{SAMPLE} = 2\text{ MHz}$, unless otherwise noted.

TERMINOLOGY

Integral Nonlinearity

The maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints of the transfer function are zero scale at 1 LSB below the first code transition, and full scale at 1 LSB above the last code transition.

Differential Nonlinearity

The difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Offset Error

The deviation of the first code transition (00...000) to (00...001) from the ideal (AGND + 1 LSB).

Gain Error

The deviation of the last code transition (111...110) to (111...111) from the ideal ($V_{REF} - 1$ LSB) after the offset error has been adjusted out.

On Resistance

A measure of the ohmic resistance between the drain and the source of the switch drivers.

CIRCUIT INFORMATION

The AD7877 is a complete, 12-bit data acquisition system for digitizing positional inputs from a touch screen in PDAs and other devices. In addition, it can monitor two battery voltages, ambient temperature, and three auxiliary analog voltages, with high and low limit comparisons on three of the inputs, and has up to four general-purpose logic I/O pins.

The core of the AD7877 is a high speed, low power, 12-bit analog-to-digital converter (ADC) with input multiplexer, on-chip track-and-hold, and on-chip clock. The results of conversions are stored in 11 results registers, and the results from one auxiliary input and two battery inputs can be compared with high and low limits stored in limit registers to generate an out-of-limit ALERT. The AD7877 also contains low resistance analog switches to switch the X and Y excitation voltages to the touch screen, a STOPACQ pin to control the ADC acquisition period, 2.5 V reference, on-chip temperature sensor, and 8-bit DAC to control LCD contrast. The high speed SPI serial bus provides control of, and communication with, the device.

Operating from a single supply from 2.2 V to 5 V, the AD7877 offers throughput rates of up to 125 kHz. The device is available in a 5 mm × 5 mm, 32-lead, lead frame chip scale package (LFCSP), and in a 2.5 mm × 2.8 mm, wafer level chip scale package (WLCSP), with a 5 × 5 ball grid array.

The data acquisition system of the AD7877 has a number of advanced features:

- Input channel sequenced automatically or selected by the host.
- STOPACQ feature to reduce noise from LCD.
- Averaging of from 1 to 16 conversions for noise reduction.
- Programmable acquisition time.
- Power management.
- Programmable ADC power-up delay before first conversion.
- Choice of internal or external reference.
- Conversion at preprogrammed intervals.

TOUCH SCREEN PRINCIPLES

A 4-wire touch screen consists of two flexible, transparent, resistive-coated layers that are normally separated by a small air gap. The X layer has conductive electrodes running down the left and right edges, allowing the application of an excitation voltage across the X layer from left to right.

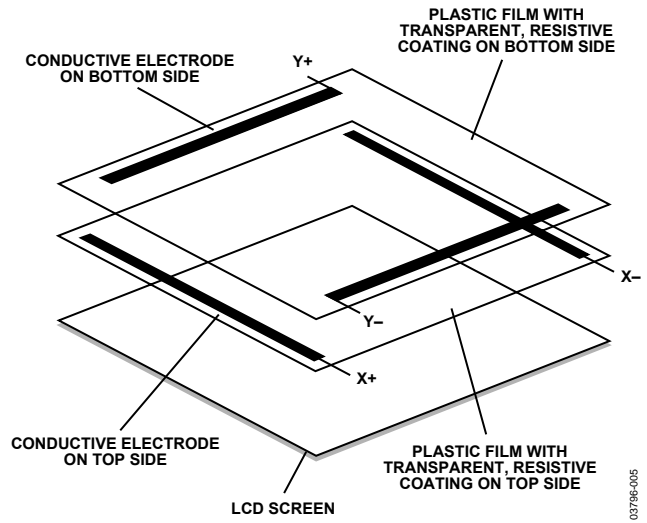

Figure 27. Basic Construction of a Touch Screen

The Y layer has conductive electrodes running along the top and bottom edges, allowing the application of an excitation voltage down the Y layer from top to bottom.

Provided that the layers are of uniform resistivity, the voltage at any point between the two electrodes is proportional to the horizontal position for the X layer and the vertical position for the Y layer.

When the screen is touched, the two layers make contact. If only the X layer is excited, the voltage at the point of contact, and therefore the horizontal position, can be sensed at one of the Y layer electrodes. Similarly, if only the Y layer is excited, the voltage, and therefore the vertical position, can be sensed at one of the X layer electrodes. By switching alternately between X and Y excitation and measuring the voltages, the X and Y coordinates of the contact point can be found.

In addition to measuring the X and Y coordinates, it is also possible to estimate the touch pressure by measuring the contact resistance between the X and Y layers. The AD7877 is designed to facilitate this measurement.

Figure 28 shows an equivalent circuit of the analog input structure of the AD7877, showing the touch screen switches, the main analog multiplexer, the ADC with analog and differential reference inputs, and the dual 3-to-1 multiplexer that selects the reference source for the ADC.

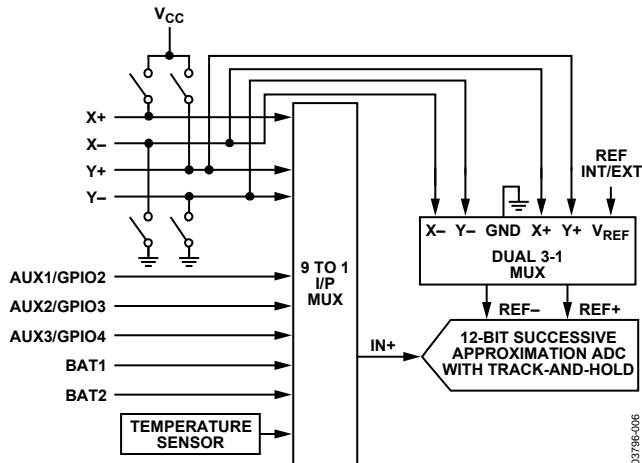

Figure 28. Analog Input Structure

The AD7877 can be set up to automatically convert either specific input channels or a sequence of channels. The results of the ADC conversions are stored in the results registers. See the Serial Interface section for details.

When measuring the ancillary analog inputs (AUX1 to AUX3, BAT1 and BAT2), the ADC uses the internal reference, or an external reference applied to the V_{REF} pin, and the measurement is referred to GND.

MEASURING TOUCH SCREEN INPUTS

When measuring the touch screen inputs, it is possible to measure using the internal (or external) reference, or to use the touch screen excitation voltage as the reference and perform a ratiometric, differential measurement. The differential method is the default and is selected by clearing the SER/DFR bit (Bit 11) in Control Register 1. The single-ended method is selected by setting this bit.

Single-Ended Method

Figure 29 illustrates the single-ended method for the Y position. For the X position, the excitation voltage is applied to X+ and X- and the voltage measured at Y+.

Figure 29. Single-Ended Conversion of Touch Screen Inputs

The voltage seen at the input to the ADC in Figure 29 is

$$V_{IN} = V_{CC} \times \frac{R_{Y-}}{R_{YTOTAL}} \quad (1)$$

The advantage of the single-ended method is that the touch screen excitation voltage can be switched off once the signal is acquired. Because a screen can draw over 1 mA, this is a significant consideration for a battery-powered system.

The disadvantages of the single-ended method are as follows:

- It can be used only if V_{CC} is close to V_{REF} . If V_{CC} is greater than V_{REF} , some positions on the screen are outside the range of the ADC. If V_{CC} is less than V_{REF} , the full range of the ADC is not used.
- The ratio of V_{CC} to V_{REF} must be known. If V_{REF} and/or V_{CC} vary relative to one another, this can introduce errors.
- Voltage drops across the switches can introduce errors. Touch screens can have a total end-to-end resistance ranging from 200 Ω to 900 Ω . Taking the lowest screen resistance of 200 Ω and a typical switch resistance of 14 Ω can reduce the apparent excitation voltage to $200/228 \times 100 = 87\%$ of its actual value. In addition, the voltage drop across the low-side switch adds to the ADC input voltage. This introduces an offset into the input voltage, thus, it can never reach zero.

The single-ended method is adequate for applications that use a fairly blunt and imprecise instrument for an input device, such as a finger.

Ratiometric Method

The ratiometric method illustrated in Figure 30 shows the negative input of the ADC reference tied to Y- and the positive input connected to Y+. Thus, the screen excitation voltage provides the reference for the ADC. The input of the ADC is connected to X+ to determine the Y position.

Figure 30. Ratiometric Conversion of Touch Screen Inputs

For greater accuracy, the ratiometric method has two significant advantages:

- The reference to the ADC is provided from the actual voltage across the screen; therefore, when the voltage drops across the switches, it has no effect.
- Because the measurement is ratiometric, it does not matter if the voltage across the screen varies in the long term. However, it must not change after the signal has been acquired.

The disadvantage of the ratiometric method is that the screen must be powered up at all times because it provides the reference voltage for the ADC.

TOUCH-PRESSURE MEASUREMENT

The pressure applied to the touch screen via a pen or finger can also be measured with the AD7877 using some simple calculations. The contact resistance between the X and Y plates is measured providing a good indication of the size of the depressed area and, therefore, the applied pressure. The area of the spot that is touched is proportional to the size of the object touching it. The size of this resistance (R_{TOUCH}) can be calculated using two different methods.

First Method

The first method requires the user to know the total resistance of the X-plate tablet (R_X). Three touch screen conversions are required:

- Measurement of the X position, $X_{POSITION}$ (Y+ input).
- Measurement of the Y- input with the excitation voltage applied to Y+ and X- (Z1 measurement).
- Measurement of the X+ input with the excitation voltage applied to Y+ and X- (Z2 measurement).

These three measurements are illustrated in Figure 31.

The AD7877 has two special ADC channel settings that configure the X and Y switches for Z1 and Z2 measurement and store the results in the Z1 and Z2 results registers. The Z1 measurement is ADC Channel 1010b, and the result is stored in the register with Read Address 11010b. The Z2 measurement is ADC Channel 0010b, and the result is stored in the register with Read Address 10010b.

The touch resistance can then be calculated using the following equation:

$$R_{TOUCH} = (R_{XPlate}) \times (X_{POSITION} / 4096 \times [Z2/Z1] - 1) \quad (2)$$

Figure 31. Three Measurements Required for Touch Pressure

Second Method

The second method requires the user to know the resistance of the X-plate and Y-plate tablets. Three touch screen conversions are required, a measurement of the X position ($X_{POSITION}$), Y position ($Y_{POSITION}$), and Z1 position.

The following equation also calculates the touch resistance:

$$R_{TOUCH} = R_{XPlate} \times (X_{POSITION} / 4096) \times [(4096/Z1) - 1] - R_{YPlate} \times [1 - (Y_{POSITION}/4096)] \quad (3)$$

STOPACQ PIN

As previously explained in the Touch Screen Principles section, touch screens are composed of two resistive layers, normally placed over an LCD screen. Because these layers are in close proximity to the LCD screen, noise can be coupled from the screen onto these resistive layers, causing errors in the touch screen positional measurements.

For example, a jitter might be noticeable in the cursor on-screen. In most LCD touch screen systems, a signal, such as an LCD invert signal or other control signal, is present, and noise is usually coupled onto the touch screen during the active period of this signal (see Figure 32).

Figure 32. Effect of LCD Noise on Touch Screen Measurements

It is only during the sample or acquisition phase of the ADC operation of the AD7877 that noise from the LCD screen has an effect on the ADC measurements. During the hold or conversion phase, the noise has no effect, because the voltage at the input of the ADC has already been acquired. Therefore, to minimize the effect of noise on the touch screen measurements, the ADC acquisition phase should be halted.

The LCD control signal should be applied to the STOPACQ pin. To ensure that acquisition never occurs during the noisy period when the LCD signal is active, the AD7877 monitors this signal. No acquisitions take place when the control signal is active. Any acquisition that is in progress when the signal becomes active is aborted and restarts when the signal becomes inactive again.

To accommodate signals of different polarities on the STOPACQ pin, a user-programmable register bit is used to indicate whether the signal is active high or low. The POL bit is Bit 3 in Control Register 2, Address 0x02. Setting POL to 1 indicates that the signal on STOPACQ is active high; setting POL to 0 indicates that it is active low. POL defaults to 0 on power-up. To disable monitoring of STOPACQ, the pin should be tied low if POL = 1, or tied high if POL = 0. Under no circumstances should the pin be left floating.

The signal on STOPACQ has no effect while the ADC is in conversion mode, or during the first conversion delay time. (See the Control Registers section for details on the first conversion delay.)

When enabled, the STOPACQ monitoring function is implemented on all input channels to the ADC: AUX1, AUX2, BAT1, BAT2, TEMP1, and TEMP2, as well as on the touch screen input channels.

TEMPERATURE MEASUREMENT

Two temperature measurement options are available on the AD7877: the single conversion method and the differential conversion method. The single conversion method requires only a single measurement on ADC Channel 1000b. Whereas differential conversion requires two measurements, one on ADC Channel 1000b and a second on ADC Channel 1001b. The results are stored in the results registers with Address 11000b (TEMP1) and Address 11001b (TEMP2). The AD7877 does not provide an explicit output of the temperature reading; the system must perform some external calculations. Both methods are based on an on-chip diode measurement.

Single Conversion Method

The single conversion method makes use of the fact that the temperature coefficient of a silicon diode is approximately $-2.1 \text{ mV}/^\circ\text{C}$. However, this small change is superimposed on the diode forward voltage, which can have a wide tolerance. It is, therefore, necessary to calibrate by measuring the diode voltage at a known temperature to provide a baseline from which the change in forward voltage with temperature can be

measured. This method provides a resolution of approximately 0.3°C and a predicted accuracy of $\pm 2.5^\circ\text{C}$.

The temperature limit comparison is performed on the result in the TEMP1 results register, which is simply the measurement of the diode forward voltage. The values programmed into the high and low limits should be referenced to the calibrated diode forward voltage to make accurate limit comparisons. An example is shown in the Limit Comparison section.

Differential Conversion Method

The differential conversion method is a 2-point measurement. The first measurement is performed with a fixed bias current into a diode (when the TEMP1 channel is selected), and the second measurement is performed with a fixed multiple of the bias current into the same diode (when the TEMP2 channel is selected). The voltage difference in the diode readings is proportional to absolute temperature and is given by the following formula:

$$\Delta V_{BE} = (kT/q) \times (\ln N) \quad (4)$$

where:

V_{BE} represents the diode voltage.

N is the bias current multiple (typical value for AD7877 = 120).

k is Boltzmann's constant.

q is the electron charge.

This method provides a resolution of approximately 1.6°C , and a guaranteed accuracy of $\pm 4^\circ\text{C}$ without calibration. Determination of the N value on a part-by-part basis improves accuracy.

Assuming a current multiple of 120, which is a typical value for the AD7877, taking Boltzmann's constant, $k = 1.38054 \times 10^{-23}$ electrons $\text{V}/^\circ\text{K}$, the electron charge $q = 1.602189 \times 10^{-19}$, then T , the ambient temperature in Kelvin, would be calculated as follows:

$$\begin{aligned} \Delta V_{BE} &= (kT/q) \times (\ln N) \\ T^\circ\text{K} &= (\Delta V_{BE} \times q) / (k \times \ln N) \\ &= (\Delta V_{BE} \times 1.602189 \times 10^{-19}) / (1.38054 \times 10^{-23} \times 4.65) \\ T^\circ\text{C} &= 2.49 \times 120 \times \Delta V_{BE} - 273 \end{aligned}$$

ΔV_{BE} is calculated from the difference in readings from the first conversion to the second conversion. The user must perform the calculations to get ΔV_{BE} , and then calculate the temperature value in degrees. Figure 33 shows a block diagram of the temperature measurement circuit.

Figure 33. Block Diagram of Temperature Measurement Circuit

Temperature Calculations

If an explicit temperature reading in °C is required, then this is calculated as follows for the single measurement method:

1. Calculate the scale factor of the ADC in degrees per LSB:

$$\text{Degrees per LSB} = \text{ADC LSB size} / -2.1 \text{ mV} = (V_{REF}/4096) / -2.1 \text{ mV}$$
2. Save the ADC output, D_{CAL} , at the Calibration Temperature T_{CAL}
3. Take ADC reading, D_{AMB} , at the temperature to be measured, T_{AMB}
4. Calculate the difference in degrees between T_{CAL} and T_{AMB} using

$$\Delta T = (D_{AMB} - D_{CAL}) \times \text{degrees per LSB}$$
5. Add ΔT to T_{CAL}

Example:

The internal 2.5 V reference is used.

1. $\text{Degrees per LSB} = (2.5/4096) / -2.1 \times 10^{-3} = -0.291$
2. The ADC output is 983 decimal at 25°C, equivalent to a diode forward voltage of 0.6 V
3. The ADC output at T_{AMB} is 880
4. $\Delta T = (880 - 983) \times -0.291 = 30^\circ$
5. $T_{AMB} = 25 + 30 = 55^\circ\text{C}$

To calculate the temperature explicitly using the differential method:

1. Calculate the LSB size of the ADC in V:

$$\text{LSB} = V_{REF}/4096$$
2. Subtract TEMP1 from TEMP2 and multiply by LSB size to get ΔV_{BE}
3. Multiply by 2490 and subtract 273 to obtain the temperature in °C

Example:

The internal 2.5 V reference is used.

1. $\text{LSB size} = 2.5 \text{ V}/4096 = 6.1 \times 10^{-4} \text{ V} (610 \mu\text{V})$
2. $TEMP1 = 880$ and $TEMP2 = 1103$:

$$\Delta V_{BE} = (1103 - 880) \times 6.1 \times 10^{-4} = 0.136 \text{ V}$$
3. $T = 0.136 \times 2490 - 273 = 65^\circ\text{C}$

BATTERY MEASUREMENT

The AD7877 can monitor battery voltages from 0.5 V to 5 V on two inputs, BAT1 and BAT2. Figure 34 shows a block diagram of a battery voltage monitored through the BAT1 pin. The voltage to the V_{CC} pin of the AD7877 is maintained at the desired supply voltage via the dc/dc regulator while the input to the regulator is monitored. This voltage on BAT1 is divided down by 2 internally, so that a 5 V battery voltage is presented to the ADC as 2.5 V. To conserve power, the divider circuit is on only during the sampling of a voltage on BAT1. The BAT2 input circuitry is identical.

The BAT1 input is ADC Channel 0110b and the result is stored in Register 10110b. The BAT2 input is ADC Channel 0111b and the result is stored in Register 10111b.

Figure 34. Block Diagram of Battery Measurement Circuit

Figure 34 shows the ADC using the internal reference of 2.5 V. The maximum battery voltage that the AD7877 can measure changes when a different reference voltage is used. The maximum voltage that is measurable is $V_{REF} \times 2$, because this voltage gives a full-scale output from the ADC. If a smaller reference is used, such as 2 V, then the maximum measurable battery voltage is 4 V. If a larger reference is used, such as 3.5 V, then the maximum measurable battery voltage is 7 V. The internal reference is particularly suited for use when measuring lithium-ion batteries, wherein the minimum voltage is about 2.7 V and the maximum voltage is about 4.2 V. A proper choice of external reference ensures that other voltage ranges can be accommodated.

AUXILIARY INPUTS

The AD7877 has three auxiliary analog inputs, AUX1 to AUX3. These channels have a full-scale input range from 0 V to V_{REF} . The ADC channel addresses for AUX1 to AUX3 are 0011b, 0100b, and 0101b, and the results are stored in Register 10011b, Register 10100b, and Register 10101b. These pins can also be reconfigured as general-purpose logic inputs/outputs, as described in the GPIO Configuration section.

LIMIT COMPARISON

The AUX1 measurement, the two battery measurements, and the TEMP1 measurement can all be compared with high and low limits, and an out-of-limit result that generates an alarm output at the ALERT pin. The limits are stored in registers with addresses from 00100b to 01011b. After a measurement from any one of the four channels is converted, it is compared with the corresponding high and low limits. An out-of-limit result sets one of the status bits in the alert status/enable register. For details on these and other registers, see the Register Maps and Detailed Register Descriptions sections. For details on writing and reading data, see the Serial Interface section.

As described in the Single Conversion Method section, the temperature comparison is made using the result of the TEMP1 measurement, that is, the diode forward voltage. Because the temperature coefficient of the diode is known but the actual forward voltage can have a wide tolerance, it is not possible to program the high and low limit registers with predetermined values.

Instead, it is necessary to calibrate the temperature measurement, calculate the TEMP1 readings at the high and low limit temperatures, and then program those values into the limit registers, as follows:

1. Calculate

$$LSB \text{ per degree} = -2.1 \text{ mV} / (V_{REF} / 4096).$$
2. Save the calibration reading D_{CAL} at Calibration Temperature T_{CAL} .
3. Subtract T_{CAL} from limit temperatures T_{HIGH} and T_{LOW} to get the difference in degrees between the limit temperatures and the calibration temperature.
4. Multiply this value by LSB per degree to obtain the value in LSBs.
5. Add these values to the digital value at the calibration temperature to get the digital high and low limit values.

Example:

The internal 2.5 V reference is used.

1. $T_{HIGH} = +65^{\circ}\text{C}$ and $T_{LOW} = -10^{\circ}\text{C}$.
2. $LSB \text{ per degree} = -2.1 \times 10^{-3} / (2.5 / 4096) = -3.44.$
3. $D_{CAL} = 983$ decimal at 25°C .
4. $D_{HIGH} = (65 - 25) \times -3.44 + 983 = 845.$
5. $D_{LOW} = (-10 - 25) \times -3.44 + 983 = 1103.$

CONTROL REGISTERS

Control Register 1 contains the ADC channel address, the SER/DFR bit (to choose single or differential methods of touch screen measurement), the register read address, and the ADC mode bits. Control Register 1 should always be the last register to be programmed prior to starting conversions. Its power-on default value is 0x00. To change any parameter after conversion has begun, the part should first be put into Mode 00, the changes made, and then Control Register 1 reprogrammed, ensuring that it is always the last register to be programmed before conversions begin.

Figure 36. Control Register 2

CONTROL REGISTER 1

ADC Mode (Control Register 1, Bits<1:0>)

These bits select the operating mode of the ADC. The AD7877 has three operating modes. These are selected by writing to the mode bits in Control Register 1. If the mode bits are 00, no conversion is performed.

Table 5. Control Register 1 Mode Selection

| Mode 1 | Mode 0 | Function |
|--------|--------|---|
| 0 | 0 | Do not convert (default) |
| 0 | 1 | Single-channel conversion, AD7877 in slave mode |
| 1 | 0 | Sequence 0, AD7877 in slave mode |
| 1 | 1 | Sequence 1, AD7877 in master mode |

If the mode bits are 01, a single conversion is performed on the channel selected by writing to the channel bits of Control Register 1 (Bit 7 to Bit 10). At the end of the conversion, if the TMR bits in Control Register 2 are set to 00, the mode bits revert to 00 and the ADC returns to no convert mode until a new conversion is initiated by the host. Setting the TMR bits to a value other than 00 causes the conversion to be repeated, as described in the Timer (Control Register 2, Bits<1:0>) section. The flowchart in Figure 38 shows how the AD7877 operates in Mode 01.

The AD7877 can also be programmed to convert a sequence of selected channels automatically. The two modes for this type of conversion are slave mode and master mode.

For slave mode operation, the channels to be digitized are selected by setting the corresponding bits in Sequencer Register 0. Conversion is initiated by writing 10b to the mode bits of Control Register 1. The ADC then digitizes the selected channels and stores the results in the corresponding results registers. At the end of the conversion, if the TMR bits in Control Register 2 are set to 00, the mode bits revert to 00 and the ADC returns to no convert mode until a new conversion is initiated by the host. Setting the TMR bits to a code other than 00 causes the conversion sequence to be repeated. The flowchart in Figure 39 shows how the AD7877 operates in Mode 10.

For master mode operation, the channels to be digitized are written to Sequencer Register 1. Master mode is then selected by writing 11 to the mode bits in Control Register 1. In this mode, the wake-up on touch feature is active, so conversion does not begin immediately. The AD7877 waits until the screen is touched before beginning the sequence of conversions. The ADC then digitizes the selected channels, and the results are written to the results registers. The AD7877 waits for the screen to be touched again, or for a timer event if the screen remains touched, before beginning another sequence of conversions. The flowchart in Figure 40 shows how the AD7877 operates in Mode 11.

ADC Channel (Control Register 1, Bits<10:7>)

The ADC channel is selected by Bits <10:7> of Control Register 1 (CHADD3 to CHADD0). In addition, the SER/DFR bit, Bit 11, selects between single-ended and differential conversion. A complete list of channel addresses is given in Table 6.

For Mode 0 (single-channel) conversion, the channel is selected by writing the appropriate CHADD3 to CHADD0 code to Control Register 1.

For sequential channel conversion, channels to be converted are selected by setting bits corresponding to the channel number in Sequencer Register 1 for slave mode sequencing or Sequencer Register 2 for master mode sequencing.

For both single-channel and sequential conversion, normal (single-ended) conversion is selected by clearing the SER/DFR bit in Control Register 1. Ratiometric (differential) conversion is selected by setting the SER/DFR bit.

Table 6. Codes for Selecting Input Channel and Normal or Ratiometric Conversion

| Channel | SER/DFR | CHADD(3:0) | Analog Input | X Switches | Y Switches | +REF | -REF |
|---------|---------|------------|-----------------|-----------------|---------------|------------------|------|
| 0 | 0 | 0 0 0 0 | X+ (Y position) | Off | On | Y+ | Y- |
| 1 | 0 | 0 0 0 1 | Y+ (X position) | On | Off | X+ | X- |
| 2 | 0 | 0 0 1 0 | Y- (Z2) | X+ off, X- on | Y+ on, Y- off | Y+ | X- |
| 3 | 0 | 0 0 1 1 | AUX1 | Off | Off | V _{REF} | GND |
| 4 | 0 | 0 1 0 0 | AUX2 | Off | Off | V _{REF} | GND |

| - | 1 | 1 1 1 1 | | Invalid address | | | |

CONTROL REGISTER 2

Timer (Control Register 2, Bits<1:0>)

The TMR bits in Control Register 2 enable the ADC to repeatedly perform a conversion or conversion sequence either once only or at intervals of 512 μ s, 1.024 ms, or 8.19 ms. In slave mode, the timer starts as soon as the conversion sequence is finished. In master mode, the timer starts at the end of a conversion sequence only if the screen remains touched. If the touch is released at any stage, then the timer stops and, the next time the screen is touched, a conversion sequence begins immediately.

Table 7. Control Register 2 Timer Selection

| TMR1 | TMRO | Function |
|------|------|---------------------------------|
| 0 | 0 | Convert only once (default) |
| 0 | 1 | Every 1024 clocks (512 μ s) |
| 1 | 0 | Every 2048 clocks (1.024 ms) |
| 1 | 1 | Every 16,384 clocks (8.19 ms) |

Int/Ext Reference (Control Register 2, Bit<2>)

If the REF bit in Control Register 2 is 0 (default value), the internal reference is selected. Buffer any connection made to V_{REF} while the internal reference is selected (for example, to supply a reference to other circuits). An external power supply should not be connected to this pin while REF is equal to 0, because it might overdrive the internal reference. Because the internal reference is 2.5 V, it operates only with supply voltages down to 2.7 V. Below this value, use an external reference.

If the REF bit is 1, the V_{REF} pin becomes an input and the internal reference is powered down. This overrides any setting of the PM bits with regard to the reference. An external reference can then be applied to the REF pin.

STOPACQ Polarity (Control Register 2, Bit<3>)

This bit should be set according to the polarity of the signal applied to the STOPACQ pin. If that signal is active high, that is, no acquisitions should occur during the high period of the signal, then the POL bit should be set to 1. If the signal is active low, then the POL bit should be 0. The default value for POL is 0.

First Conversion Delay (Control Register 2, Bits<5:4>)

The first conversion delay (FCD) bits in Control Register 2 program a delay of 500 ns (default), 128 μ s, 1.024 ms, or 8.19 ms before the first conversion, to allow the ADC time to power up. This delay also occurs before conversion of the X and Y coordinate channels, to allow extra time for screen settling, and after the last conversion in a sequence, to precharge PENIRQ. If the signal on the STOPACQ pin is being monitored and goes active during the FCD, it is ignored until after the FCD period.

Table 8. First Conversion Delay Selection

| FCD1 | FCD | Function |
|------|-----|--------------------------------|
| 0 | 0 | 1 clock delay (500 ns) |
| 0 | 1 | 256 clock delays (128 μ s) |
| 1 | 0 | 2048 clock delays (1.024 ms) |
| 1 | 1 | 16,384 clock delays (8.19 ms) |

Power Management (Control Register 2, Bits<7:6>)

The power management (PM) bits in Control Register 2 allow the power management features of the ADC to be programmed. If the PM bits are 00, the ADC is powered down permanently. This overrides any setting of the mode bits in Control Register 1. If the PM bits are 01, the ADC and the reference both power down when the ADC is not converting. If the PM bits are 10, the ADC and reference are powered up continuously. If the PM bits are 11, the ADC, but not the reference, powers down when the ADC is not converting.

Table 9. Power Management Selection

| PM1 | PM0 | Function |
|-----|-----|---|
| 0 | 0 | Power down continuously (default) |
| 0 | 1 | Power down ADC and reference when ADC is not converting (powers up with FCD at start of a conversion) |
| 1 | 0 | Powered up continuously |
| 1 | 1 | Power down ADC when ADC is not converting (powers up with FCD at start of conversion) |

Acquisition Time (Control Register 2, Bits<9:8>)

The ACQ bits in Control Register 2 allow the selection of acquisition times for the ADC of 2 μ s (default), 4 μ s, 8 μ s, or 16 μ s. The user can program the ADC with an acquisition time suitable for the type of signal being sampled. For example, signals with large RC time constants can require longer acquisition times.

Table 10. Acquisition Time Selection

| ACQ1 | ACQ0 | Function |
|------|------|-------------------------------|
| 0 | 0 | 4 clock periods (2 μ s) |
| 0 | 1 | 8 clock periods (4 μ s) |
| 1 | 0 | 16 clock periods (8 μ s) |
| 1 | 1 | 32 clock periods (16 μ s) |

Averaging (Control Register 2, Bits<11:10>)

Signals from touch screens can be extremely noisy. The AVG bits in Control Register 2 allow multiple conversions to be performed on each input channel and averaged to reduce noise. A single conversion can be selected (no averaging), which is the default, or 4, 8, or 16 conversions can be averaged. Only the final averaged result is written into the results register.

Table 11. Averaging Selection

| AVG1 | AVG0 | Function |
|------|------|--------------------------------------|
| 0 | 0 | ADC performs 1 average per channel |
| 0 | 1 | ADC performs 4 averages per channel |
| 1 | 0 | ADC performs 8 averages per channel |
| 1 | 1 | ADC performs 16 averages per channel |

SEQUENCER REGISTERS

There are two sequencer registers on the AD7877. Sequencer Register 0 controls the measurements performed during a slave mode sequence. Sequencer Register 1 controls the measurements performed during a master mode sequence.

To include a measurement in a slave mode or master mode sequence, the relevant bit must be set in Sequencer Register 0 or Sequencer Register 1. Setting Bit 11 includes a measurement on ADC Channel 0 in the sequence, which is the Y positional measurement. Setting Bit 10 includes a measurement on ADC Channel 1 (X+ measurement), and so on, through Bit 1 for Channel 10. Figure 37 illustrates the correspondence between the bits in the sequencer registers and the various measurements. Bit 0 in both sequencer registers is not used. See also the Detailed Register Descriptions section.

Figure 40. Master Mode Sequencer Operation

INTERRUPTS

Data Available Output (DAV)

The data available output (\overline{DAV}) indicates that new ADC data is available in the results registers. While the ADC is idle or is converting, \overline{DAV} is high. Once the ADC has finished converting and new data has been written to the results registers, \overline{DAV} goes low. Taking \overline{DAV} low to read the registers resets \overline{DAV} to a high condition. \overline{DAV} is also reset, if a new conversion is started by the AD7877 because the timer expired. The host should attempt to read the results registers only when \overline{DAV} is low.

Figure 41. Operation of DAV Output

\overline{DAV} is useful as a host interrupt in master mode. In this mode, the host can program the AD7877 to automatically perform a sequence of conversions, and can be interrupted by \overline{DAV} at the end of each conversion sequence.

When the on-board timer is programmed to perform automatic conversions, a limited time is available to the host to read the results registers before another sequence of conversions begins. The \overline{DAV} signal is reset high when the timer expires, and the host should not access the results registers while \overline{DAV} is high.

Figure 42 shows the worst-case timings for reading the results registers after \overline{DAV} has gone low. The timer is set at a minimum, and the conversion sequence includes all 11 possible ADC channels. t_1 is the time taken for acquisition and conversion on one ADC channel. t_2 shows the minimum timer delay, that is, 1024 clock periods. t_3 is the time taken to read all 11 result registers. If the host wants to read all 11 registers, then it must do so before the timer expires. t_4 is the maximum time allowable between \overline{DAV} going low and the host beginning to read the results registers. If t_4 is exceeded, then all registers cannot be read before the start of a new conversion, and incorrect data could be read by the host.

Figure 42. Timing for Reads after \overline{DAV} Goes Low

If $f_{DCLK} = 20 \text{ MHz}$ (maximum), then $t_{DCLK} = 50 \text{ ns}$.

$$t_2 = 512 \mu\text{s} \text{ with timer set to } 1024 \text{ (TMR bits} = 01\text{b)}$$

$$t_{WRITE} = t_{READ} = 16 \text{ clk period} \times t_{DCLK} = 800 \text{ ns}$$

$t_3 =$ maximum time taken to write read address and read 11 registers = $800 \text{ ns (write)} + [800 \text{ ns (read)} \times 11] = 9.6 \mu\text{s}$.

$$t_{4MAX} = t_2 - t_3 = 512 \mu\text{s} - 9.6 \mu\text{s} = 502.4 \mu\text{s}$$

Pen Interrupt ($\overline{\text{PENIRQ}}$)

The pen interrupt request output ($\overline{\text{PENIRQ}}$) goes low whenever the screen is touched. The pen interrupt equivalent output circuitry is outlined in Figure 43. This is a digital logic output with an internal pull-up resistor of $50 \text{ k}\Omega$, which means it does not need an external pull-up. The $\overline{\text{PENIRQ}}$ output idles high. The $\overline{\text{PENIRQ}}$ circuitry is always enabled, except during conversions.

Figure 43. $\overline{\text{PENIRQ}}$ Output Equivalent Circuit

When the screen is touched, $\overline{\text{PENIRQ}}$ goes low. This generates an interrupt request to the host. When the screen touch ends, and if the ADC is idle, $\overline{\text{PENIRQ}}$ immediately goes high. If the ADC is converting, $\overline{\text{PENIRQ}}$ goes high once the ADC becomes idle. The $\overline{\text{PENIRQ}}$ operation for these two conditions is shown in Figure 44.

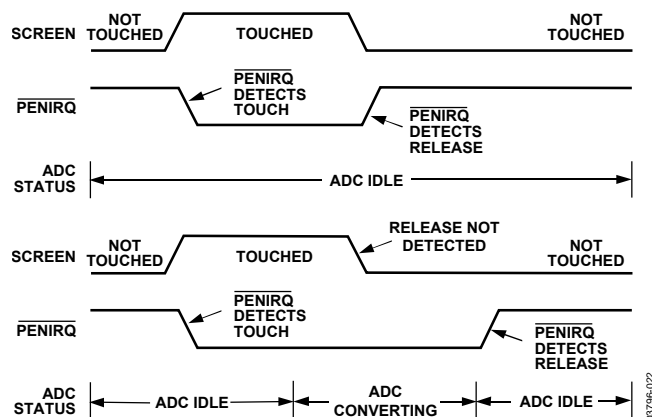

Figure 44. $\overline{\text{PENIRQ}}$ Operation for ADC Idle and ADC Converting

SYNCHRONIZING THE AD7877 TO THE HOST CPU

The two suggested methods for synchronizing the AD7877 to its host CPU are slave mode, in which the mode bits can be either 01b or 10b, and master mode, in which the mode bits are 11b.

In slave mode, $\overline{\text{PENIRQ}}$ can be used as an interrupt to the host. When $\overline{\text{PENIRQ}}$ goes low to indicate that the screen has been touched, the host is awakened. The host can then program the AD7877 to begin converting in either Mode 01b or Mode 10b, and can read the result registers after the conversions are completed.

In master mode, $\overline{\text{DAV}}$ can also be used as an interrupt to the host. However, the host should first initialize the AD7877 in Mode 11b. The host can then go into sleep mode to conserve power. The wake-up on touch feature of the AD7877 is active in this mode, therefore, when the screen is touched, the programmed sequence of conversions begins automatically. When the $\overline{\text{DAV}}$ signal asserts, the host reads the new data available in the AD7877 results registers and returns to sleep mode. This method can significantly reduce the load on the host.

8-BIT DAC

The AD7877 features an on-chip 8-bit DAC for LCD contrast control. The DAC can be configured for voltage output by clearing Bit 2 of the DAC register (Address 1110b), or for current output by setting this bit.

The output voltage range can be set to 0 to $V_{CC}/2$ by clearing Bit 0 of the DAC register, or to 0 to V_{CC} by setting this bit. In current mode, the output range is selectable by an external resistor, R_{RNG} , connected between the ARNG pin and GND. This sets the full-scale output current according to the following equations:

$$I_{FS} = V_{CC}/(R_{RNG} \times 6)$$

therefore,

$$R_{RNG} = V_{CC}/(I_{FS} \times 6) \quad (5)$$

In current mode, the DAC sinks current, that is, positive current flows into ground. The maximum output current is 1000 μA . The DAC is updated by writing to Address 1110b of the DAC register. The 8 MSBs of the data-word are used for DAC data.

The most effective way to control LCD contrast with the DAC is to use it to control the feedback loop of the dc to dc converter that supplies the LCD bias voltage, as shown in Figure 45. The bias voltage for graphic LCDs is typically in the range of 20 V to 25 V, and the dc to dc converter usually has a feedback loop that attenuates the output voltage and compares it with an internal reference voltage.

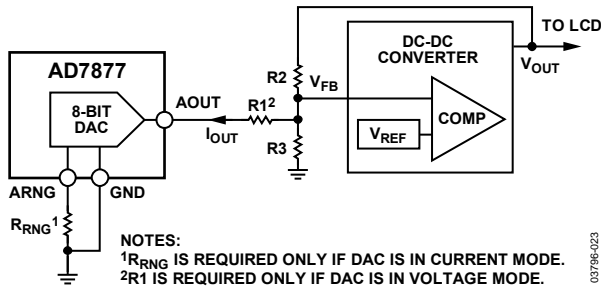

Figure 45. Using the DAC to Adjust LCD Contrast

The circuit operates as follows. If the DAC is in current mode when the DAC output is zero, it has no effect on the feedback loop. Regardless of what the DAC does, the feedback loop maintains the voltage across $R4$, V_{FB} , equal to V_{REF} , and the output voltage, V_{OUT} , is

$$V_{REF} \times (R2 + R3)/R3$$

As the DAC output is increased, it increases the feedback current, so the voltage across $R2$ and, therefore, the output voltage also increase. Note that the voltage across $R3$ does not change. This is important for calculation of the adjustment range.

In current mode, it is quite easy to calculate the resistor values to give the required adjustment range in V_{OUT} using the following steps:

1. Find the required maximum and minimum values of V_{OUT} from the LCD manufacturer's data
2. Decide on the current around the feedback loop. For reasonable accuracy of the output voltage, this current should be at least 100 times the input bias current of the dc-dc converter's comparator
3. Calculate $R3$ using the following equation:

$$R3 = V_{FB}/I_{FB} = V_{REF}/I_{FB}$$

4. Calculate $R2$ for the minimum value of V_{OUT} , when the DAC has no effect

$$R2 = R3(V_{OUT(MIN)} - V_{REF})/V_{REF}$$

5. Because the voltage across $R3$ does not change, subtract V_{REF} from $V_{OUT(MAX)}$ and $V_{OUT(MIN)}$ to get the maximum and minimum voltages across $R2$

6. Calculate the change in feedback current between minimum and maximum output voltages

$$\Delta I = V_{R2(MAX)}/R2 - V_{R2(MIN)}/R2$$

This is the required full-scale current of the DAC.

7. Calculate R_{RNG} from Equation 5

Example:

1. $V_{CC} = 5 \text{ V}$
 $V_{OUT(MIN)}$ is 20 V and $V_{OUT(MAX)}$ is 25 V
 V_{REF} is 1.25 V
2. Allow 100 μA around the feedback loop
3. $R3 = 1.25 \text{ V}/100 \mu\text{A} = 12.5 \text{ k}\Omega$
 Use the nearest preferred value of 12 k Ω and recalculate the feedback current as

$$I_{FB} = 1.25 \text{ V}/12 \text{ k}\Omega = 104 \mu\text{A}$$

4. $R2 = (20 \text{ V} - 1.25 \text{ V})/104 \mu\text{A} = 180 \text{ k}\Omega$
5. $\Delta I = 23.75 \text{ V}/180 \text{ k}\Omega - 18.75 \text{ V}/180 \text{ k}\Omega = 28 \mu\text{A}$
6. $R_{RNG} = 5 \text{ V}/(6 \times 28 \mu\text{A}) = 30 \text{ k}\Omega$

In voltage mode, the circuit operation depends on whether the maximum output voltage of the DAC exceeds the dc to dc converter V_{REF} .

When the DAC output voltage is zero, it sinks the maximum current through $R1$. The feedback current and, therefore, V_{OUT} are at their maximum. As the DAC output voltage increases, the

sink current and, thus, the feedback current decrease, and V_{OUT} falls. If the DAC output exceeds V_{REF} , it starts to source current, and V_{OUT} has to further decrease to compensate. When the DAC output is at full scale, V_{OUT} is at its minimum.

Note that the effect of the DAC on V_{OUT} is opposite in voltage mode to that in current mode. In current mode, increasing DAC code increases the sink current, so V_{OUT} increases with increasing DAC code. In voltage mode, increasing DAC code increases the DAC output voltage, reducing the sink current.

Calculate the resistor values as follows:

1. Decide on the feedback current as before.
2. Calculate the parallel combination of R_1 and R_3 when the DAC output is zero

$$R_P = V_{REF}/I_{FB}$$

3. Calculate R_2 as before, but use R_P and $V_{OUT(MAX)}$

$$R_2 = R_P(V_{OUT(MAX)} - V_{REF})/V_{REF}$$

4. Calculate the change in feedback current between minimum and maximum output voltages as before using

$$\Delta I = V_{R2(MAX)}/R_2 - V_{R2(MIN)}/R_2$$

This is equal to the change in current through R_1 between zero output and full scale, which is also given by

$$\begin{aligned} \Delta I &= \text{current at zero} - \text{current at full scale} \\ &= V/R_1 - (V_{REF} - V)/R_1 \\ &= V/R_1 \end{aligned}$$

$$5. \quad R_1 = V_{FS}/\Delta.$$

6. Calculate R_3 from R_1 and R_P using

$$R_3 = (R_1 \times R_P)/(R_1 - R_P)$$

Example:

1. $V_{CC} = 5 \text{ V}$ and $V_{FS} = V_{CC}$. $V_{OUT(MIN)}$ is 20 V and $V_{OUT(MAX)}$ is 25 V. V_{REF} is 1.25 V. Allow 100 μA around the feedback loop.

$$2. \quad R_P = 1.25 \text{ V}/100 \mu\text{A} = 12.5 \text{ k}\Omega.$$

$$3. \quad R_2 = 12.5 \text{ k}\Omega \times (25 \Omega - 1.25 \Omega)/1.25 \Omega = 237 \text{ k}\Omega.$$

Use nearest preferred value of 240 k Ω .

$$4. \quad \Delta I = 25 \text{ V}/240 \text{ k}\Omega - 20 \text{ V}/240 \text{ k}\Omega = 21 \mu\text{A}.$$

$$5. \quad R_1 = 5 \text{ V}/21 \mu\text{A} = 238 \text{ k}\Omega.$$

Use nearest preferred value of 250 k Ω .

$$6. \quad R_3 = (180 \text{ k}\Omega \times 12.5 \text{ k}\Omega)/(180 \text{ k}\Omega - 12.5 \text{ k}\Omega) = 13.4 \text{ k}\Omega.$$

Use nearest preferred value of 13 k Ω .

The actual adjustment range using these values is 21 V to 26 V.

SERIAL INTERFACE

The AD7877 is controlled via a 3-wire serial peripheral interface (SPI). The SPI has a data input pin (DIN) for inputting data to the device, a data output pin (DOUT) for reading data back from the device, and a data clock pin (DCLK) for clocking data into and out of the device. A chip-select pin (\overline{CS}) enables or disables the serial interface.

WRITING DATA

Data is written to the AD7877 in 16-bit words. The first four bits of the word are the register address that directs the AD7877 to the register to write to. The next 12 bits are data. How the AD7877 handles the data bits depends on the register address.

Register Address 0000b is a dummy address, which does nothing. Register Addresses 0010b to Register Address 1110b are 12-bit registers that perform various functions as described in the register map.

Register Address 1111b is not a physical register, but enables an extended writing mode that allows writing to the GPIO configuration registers. When the register address is 1111b, the next four bits of the data-word are the address of a GPIO configuration register and the eight LSBs are the GPIO configuration data. For details on the configuration of the GPIO pins, see the General-Purpose I/O Pins section.

Register Address 0001b is a physical register, Control Register 1, but this is a special register. It contains data for setting up the ADC channel and operating mode, but Bit 20 to Bit 6 compose the register address for reading. These define the register that is read back during the next read operation. Control Register 1 should be the last register in the AD7877 to be programmed before starting a conversion. The three types of data-words used for writing are shown in Figure 46.

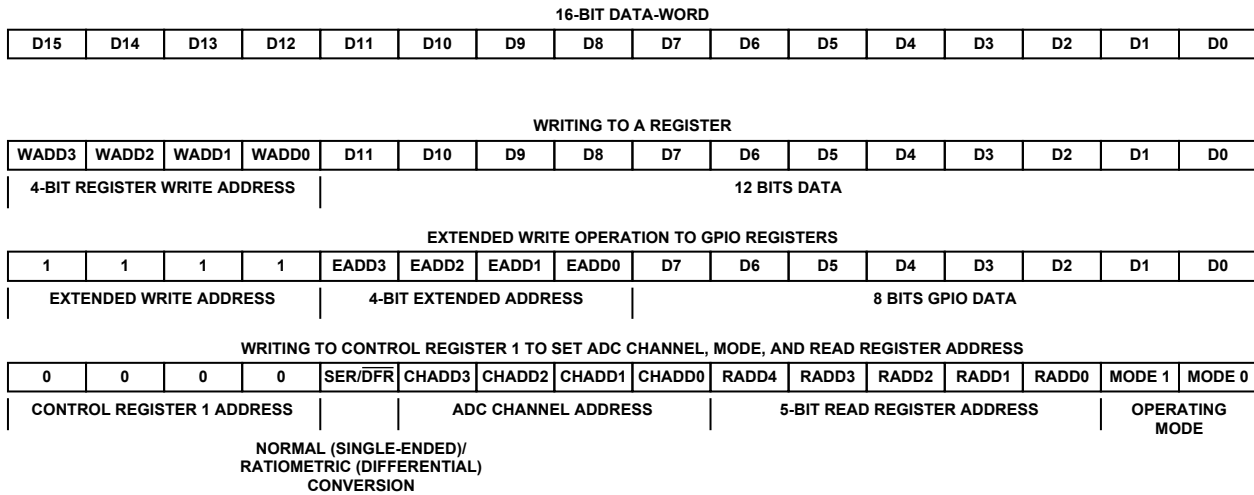

Figure 46. Designation of Data-Word Bits in AD7877 Write Operations

NOTES:

- ¹DATA IS CLOCKED OUT ON THE FALLING EDGE OF DCLK.
- ²INPUT DATA IS SAMPLED ON THE RISING EDGE OF DCLK.
- ³FOR 8-BIT REGISTERS, 8 LEADING ZEROS PRECEDE 8 BITS OF DATA.
- ⁴REGISTER READ ADDRESS INCREMENTS AUTOMATICALLY, PROVIDED THAT A NEW ADDRESS IS NOT WRITTEN TO CONTROL REGISTER 1.

Figure 47. Overall Read/Write Timing

WRITE TIMING

No serial interface operations can take place when \overline{CS} is high. To write to the AD7877, \overline{CS} must be taken low. To write to the device, a burst of 16 clock pulses is input to DCLK while the write data is input to DIN. Data is clocked in on the rising edge of DCLK. If multiple write operations are to be performed, \overline{CS} must be taken high after the end of each write operation before another write operation can be performed by taking \overline{CS} low again.

READING DATA

Data is available on the DOUT pin following the falling edge of \overline{CS} , when the device is being clocked. The MSB is clocked out on the falling edge of \overline{CS} , with subsequent data bits clocked out on the falling edge of DCLK.

After \overline{CS} is taken low and the device is clocked, the AD7877 outputs data from the register whose read address is currently stored in Control Register 1. Once this data has been output, the address increments automatically. \overline{CS} must be taken high between reads. When \overline{CS} is taken low again, reading continues

from the register whose read address is in Control Register 1, provided that a write operation does not change the address. If the register read address reaches 11111b, it is then reset to zero. This feature allows all registers to be read out in sequence without having to explicitly write all their addresses to the device.

Note that because data-words are 16 bits long, but the data registers are only 12 bits long, or 8 bits in the case of GPIO registers, the first four bits of a readback data-word are zeros, or the first 8 bits in the case of a GPIO register.

V_{DRIVE} PIN

The supply voltage to all pins associated with the serial interface (\overline{DAV} , DIN, DOUT, DCLK, \overline{CS} , \overline{PENIRQ} , and \overline{ALERT}) is separate from the main V_{CC} supply and is connected to the V_{DRIVE} pin. This allows the AD7877 to be connected directly to processors whose supply voltage is less than the minimum operating voltage of the AD7877, in fact, as low as 1.7 V.

GENERAL-PURPOSE I/O PINS

The AD7877 has one dedicated general-purpose logic input/output pin (GPIO4), and any or all of the three auxiliary analog inputs can also be reconfigured as GPIOs. Associated with the GPIOs are two 8-bit control registers and one 8-bit data register that are accessed using the extended write mode.

As described in the Reading Data section, GPIO registers are written to using the extended writing mode. The first four bits of the data-word must be 1111b to access the extended writing map, and the next four bits are the GPIO register address. This leaves 8 bits for the GPIO register data, because all GPIO registers are 8 bits.

The GPIO control registers are located at the 0000b and 0001b extended writing map addresses, and the GPIO data register is at Address 0010b. GPIO registers are read in the same way as other registers, by writing a 5-bit address to Control Register 1. The GPIO registers are located at Read Addresses 11011b to Read Address 11101b.

GPIO CONFIGURATION

Each GPIO pin is configured by four bits in one of the GPIO control registers and has a data bit in the GPIO data register. The GPIO configuration bits are described in the following sections and in Table 12. Also see the Detailed Register Descriptions section.

Enable (EN)

These bits enable or disable the GPIO pins. When EN = 0, the corresponding GPIO pin is configured as the alternate function (AUX input). The other GPIO configuration bits have no effect, if the particular GPIO is not enabled. When EN = 1, the pin is configured as a GPIO pin. GPIO4, which does not have an alternate function, does not have an EN bit; it is always enabled.

Direction—DIR

These bits set the direction of the GPIO pins. When DIR = 0, the pin is an output. Setting or clearing the relevant bit in the GPIO data register outputs a value on the corresponding GPIO pin. The output value depends on the POL bit.

When DIR = 1, the pin is an input. An input value on the relevant GPIO pin sets or clears the corresponding bit in the GPIO data register, depending on the POL bit. A GPIO data register bit is read-only when DIR = 1 for that GPIO.

Polarity (POL)

When POL = 0, the GPIO pin is active low. When POL = 1, the GPIO pin is active high. How this bit affects the GPIO operation also depends on the DIR bit.

If POL = 1 and DIR = 1, a 1 at the input pin sets the corresponding GPIO data register bit to 1. A 0 at the input pin clears the corresponding GPIO data bit to 0.

If POL = 1 and DIR = 0, a 1 in the GPIO data register bit puts a 1 on the corresponding GPIO output pin. A 0 in the GPIO data register bit puts a 0 on the GPIO output pin.

If POL = 0 and DIR = 1, a 1 at the input pin sets the corresponding GPIO data bit to 0. A 0 at the input pin clears the corresponding GPIO data bit to 1.

If POL = 0 and DIR = 0, a 1 in the GPIO data register bit puts a 0 on the corresponding GPIO output pin. A 0 in the GPIO data register bit puts a 1 on the GPIO output pin.

ALERT Enable (ALEN)

GPIOs can operate as interrupt sources to trigger the $\overline{\text{ALERT}}$ output. This is controlled by the $\overline{\text{ALERT}}$ enable (ALEN) bits in the GPIO configuration registers. When ALEN = 1, the corresponding GPIO can trigger an $\overline{\text{ALERT}}$. When ALEN = 0, the corresponding GPIO cannot cause the $\overline{\text{ALERT}}$ output to assert.

$\overline{\text{ALERT}}$ is asserted low if any GPIO data register bit is set when the GPIO is configured as an input. The GPIO data bit is set if a 1 appears on the GPIO input pin when POL = 1, or if a 0 appears on the GPIO input pin when POL = 0. $\overline{\text{ALERT}}$ is triggered only when the GPIO is configured as an input, that is, when DIR = 1. $\overline{\text{ALERT}}$ can never be triggered by a GPIO that is configured as an output, that is, DIR = 0.

ALERT Output

The $\overline{\text{ALERT}}$ pin is an alarm or interrupt output that goes low if any one of a number of interrupt sources is asserted. The results of high and low limit comparisons on the AUX1, BAT1, BAT2, and TEMP1 channels are interrupt sources. An out-of-limit comparison sets a status bit in the alert status/mask register (Address 00011b). There are separate status bits for both the high and low limits on each channel to indicate which limit was exceeded. The interrupt sources can be masked out by clearing the corresponding enable bit in this register. There is one enable bit per channel.

$\overline{\text{ALERT}}$ is also asserted if an input on a GPIO pin sets a bit in the GPIO data register, as explained in the $\overline{\text{ALERT}}$ Enable section. GPIO interrupts can be disabled by clearing the corresponding ALEN bit in the GPIO control registers.

The interrupt source can be identified by reading the GPIO data register and the alert status/enable register. $\overline{\text{ALERT}}$ remains asserted until the source of the interrupt has been masked out or removed.

If the $\overline{\text{ALERT}}$ source is a GPIO, then masking out the interrupt by clearing the corresponding ALEN bit to 0 or removing the source of the interrupt on the GPIO pin causes $\overline{\text{ALERT}}$ to go high again.

If the $\overline{\text{ALERT}}$ source is an out-of-limit measurement, writing a 0 to the corresponding status bit in the alert status/enable register causes $\overline{\text{ALERT}}$ to go high. However, the status bit is set to 1 again on the next measurement cycle, if the measurement remains out of limit. The $\overline{\text{ALERT}}$ source can also be masked by clearing the relevant bit in the alert status/enable register to 0.

Table 12. GPIO Configuration

| EN | DIR | POL | ALEN | Data Bit | Pin Voltage | $\overline{\text{ALERT}}$ |
|----|-----|-----|------|----------------|----------------|---------------------------|
| 0 | X | X | X | X | X | X |
| 1 | 0 | 0 | 0 | 0 | 1 ¹ | 1 |
| 1 | 0 | 0 | 0 | 1 | 0 ¹ | 1 |
| 1 | 0 | 0 | 1 | 0 | 1 ¹ | 1 |
| 1 | 0 | 0 | 1 | 1 | 0 ¹ | 1 |
| 1 | 0 | 1 | 0 | 0 | 0 ¹ | 1 |
| 1 | 0 | 1 | 0 | 1 | 1 ¹ | 1 |
| 1 | 0 | 1 | 1 | 0 | 0 ¹ | 1 |
| 1 | 0 | 1 | 1 | 1 | 1 ¹ | 1 |
| 1 | 1 | 0 | 0 | 1 ² | 0 | 1 |
| 1 | 1 | 0 | 0 | 0 ² | 1 | 1 |
| 1 | 1 | 0 | 1 | 1 ² | 0 | 0 |
| 1 | 1 | 0 | 1 | 0 ² | 1 | 1 |
| 1 | 1 | 1 | 0 | 0 ² | 0 | 1 |
| 1 | 1 | 1 | 0 | 1 ² | 1 | 1 |
| 1 | 1 | 1 | 1 | 0 ² | 0 | 1 |
| 1 | 1 | 1 | 1 | 1 ² | 1 | 0 |

¹ A change in the data register causes a change in the output voltage on the pin.

² A change in input voltage on the pin causes a change in the data register bit.

GROUNDING AND LAYOUT

It is recommended that the ground pins, AGND and DGND, be shorted together as close as possible to the device itself on the user's PCB.

For more information on grounding and layout considerations for the AD7877, refer to the *Layout and Grounding Recommendations for Touch Screen Digitizers Technical Note*.

PCB DESIGN GUIDELINES FOR CHIP SCALE PACKAGES

The lands on the chip scale package (CP-32) are rectangular. The printed circuit board pad for these should be 0.1 mm longer than the package land length and 0.05 mm wider than the package land width. To ensure that the solder joint size is maximized, center the land on the pad.

The bottom of the chip scale package has a central thermal pad. The thermal pad on the printed circuit board should be at least as large as this exposed pad. On the printed circuit board, provide a clearance of at least 0.25 mm between the thermal pad and the inner edges of the pad pattern to ensure that shorting is avoided.

Using thermal vias on the printed circuit board thermal pad improves the thermal performance of the package. If vias are used, incorporate them in the thermal pad at a 1.2 mm pitch grid. Keep the via diameter between 0.3 mm and 0.33 mm. The via barrel should be plated with 1 oz. copper to plug the via.

The user should connect the printed circuit board thermal pad to AGND.

DETAILED REGISTER DESCRIPTIONS

Register Name: Control Register 1

Write Address: 0001; Read Address: 00001; Default Value: 0x000; Type: Read/Write.

Table 16.

| Bit | Name | Read/Write | Description |
|-----|---------|------------|---|
| 0 | MODE0 | R/W | LSB of ADC mode code. |
| 1 | MODE1 | R/W | MSB of ADC mode code. 00 = no conversion. 01 = single conversion. 10 = conversion sequence (slave mode). 11 = conversion sequence (master mode). |
| 2 | RD0 | R/W | LSB of register read address. To read a register, its address must first be written to Control Register 1. |
| 3 | RD1 | R/W | Bit 1 of register read address. To read a register, its address must first be written to Control Register 1. |
| 4 | RD2 | R/W | Bit 2 of register read address. To read a register, its address must first be written to Control Register 1. |
| 5 | RD3 | R/W | Bit 3 of register read address. To read a register, its address must first be written to Control Register 1. |
| 6 | RD4 | R/W | MSB of register read address. To read a register, its address must first be written to Control Register 1. |
| 7 | CHADD0 | R/W | LSB of ADC channel address. |
| 8 | CHADD1 | R/W | Bit 1 of ADC channel address. |
| 9 | CHADD2 | R/W | Bit 2 of ADC channel address. |
| 10 | CHADD3 | R/W | MSB of ADC channel address. 0000 = X+ input (Y position). 0001 = Y+ input (X position). 0010 = Y- (Z2) input (used for touch-pressure calculation). 0011 = Auxiliary Input 1 (AUX1). 0100 = Auxiliary Input 2 (AUX2). 0101 = Auxiliary Input 3 (AUX3). 0110 = Battery Monitor Input 1 (BAT1). 0111 = Battery Monitor Input 2 (BAT2). 1000 = Temperature Measurement 1 (used for single conversion). 1001 = Temperature Measurement 2 (used for differential measurement method). 1010 = X+ (Z1) input (used for touch-pressure calculation). |
| 11 | SER/DFR | R/W | Selects normal (single-ended) or ratiometric (differential) conversion. 0 = ratiometric (differential). 1 = normal (single-ended). |

AD7877

Register Name: Control Register 2

Write Address: 0010; Read Address: 00010; Default Value: 0x000; Type: Read/Write.

Table 17.

| Bit | Name | Read/Write | Description |
|-----|------|------------|---|
| 0 | TMR0 | R/W | LSB of conversion interval timer |
| 1 | TMR1 | R/W | MSB of conversion interval timer 00 = convert only once 01 = every 1024 clock periods (512 μ s) 10 = every 2048 clock periods (1.024 ms) 11 = every 16,384 clock periods (8.19 ms) |
| 2 | REF | R/W | Selects internal or external reference 0 = internal reference 1 = external reference |
| 3 | POL | R/W | Indicates polarity of signal on STOPACQ pin 0 = active low 1 = active high |
| 4 | FCD0 | R/W | LSB of first conversion delay |
| 5 | FCD1 | R/W | MSB of first conversion delay This delay occurs before the first conversion after powering up the ADC, before converting the X and Y coordinate channels to allow settling, and after the last conversion to allow PENIRQ precharge 00 = 1 clock period delay (500 ns) 01 = 256 clock periods delay (128 μ s) 10 = 2048 clock periods delay (1.024 ms) 11 = 16,384 clock periods delay (8.19 ms) |
| 6 | PM0 | R/W | LSB of ADC power management code |
| 7 | PM1 | R/W | MSB of ADC power management code 00 = ADC and reference powered down continuously For the following codes, regardless of PM bits, the reference is always powered down if the REF bit is 1: 01 = ADC and reference powered down when not converting 10 = ADC and reference powered up continuously 11 = ADC powered down when not converting, reference powered up |
| 8 | ACQ0 | R/W | LSB of ADC acquisition time |
| 9 | ACQ1 | R/W | MSB of ADC acquisition time 00 = 4 clock periods (2 μ s) 01 = 8 clock periods (4 μ s) 10 = 16 clock periods (8 μ s) 11 = 32 clock periods (16 μ s) |
| 10 | AVG0 | R/W | LSB of ADC averaging code |
| 11 | AVG1 | R/W | MSB of ADC averaging code 00 = no averaging (1 conversion per channel) 01 = 4 measurements per channel averaged 10 = 8 measurements per channel averaged 11 = 16 measurements per channel averaged |

Register Name: Alert Status/Enable Register

Write Address: 0011; Read Address: 00011; Default Value: 0x000; Type: Read/Write.

Table 18.

| Bit | Name | Read/Write | Description |
|-----|---------|------------|---|
| 0 | AUX1LO | R/W | When this bit is 1, the AUX1 channel is below its low limit |
| 1 | BAT1LO | R/W | When this bit is 1, the BAT1 channel is below its low limit |
| 2 | BAT2LO | R/W | When this bit is 1, the BAT2 channel is below its low limit |
| 3 | TEMP1LO | R/W | When this bit is 1, the TEMP1 channel is above its low limit |
| 4 | AUX1HI | R/W | When this bit is 1, the AUX1 channel is above its high limit |
| 5 | BAT1HI | R/W | When this bit is 1, the BAT1 channel is above its high limit |
| 6 | BAT2HI | R/W | When this bit is 1, the BAT2 channel is above its high limit |
| 7 | TEMP1HI | R/W | When this bit is 1, the TEMP1 channel is below its high limit |
| 8 | AUX1EN | R/W | Setting this bit enables AUX1 as an interrupt source to the ALERT output |
| 9 | BAT1EN | R/W | Setting this bit enables BAT1 as an interrupt source to the ALERT output |
| 10 | BAT2EN | R/W | Setting this bit enables BAT2 as an interrupt source to the ALERT output |
| 11 | TEMP1EN | R/W | Setting this bit enables TEMP1 as an interrupt source to the ALERT output |

Register Name: AUX1 High Limit

Write Address: 0100; Read Address: 00100;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit high limit for Auxiliary Input 1.

Register Name: AUX1 Low Limit

Write Address: 0101; Read Address: 00101;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit low limit for Auxiliary Input 1.

Register Name: BAT1 High Limit

Write Address: 0110; Read Address: 00110;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit high limit for Battery Monitoring Input 1.

Register Name: BAT1 Low Limit

Write Address: 0111; Read Address: 00111;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit low limit for Battery Monitoring Input 1.

Register Name: BAT2 High Limit

Write Address: 1000; Read Address: 01000;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit high limit for Battery Monitoring Input 2.

Register Name: BAT2 Low Limit

Write Address: 1001; Read Address: 01001;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit low limit for Battery Monitoring Input 2.

Register Name: TEMP1 Low Limit

Write Address: 1010; Read Address: 01010;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit low limit for temperature measurement.

Register Name: TEMP1 High Limit

Write Address: 1011; Read Address: 01011;
Default Value: 0x000; Type: Read/Write.

This register contains the 12-bit high limit for temperature measurement.

Register Name: Sequencer Register 0

Write Address: 1100; Read Address: 01100; Default Value: 0x000; Type: Read/Write.

Table 19.

| Bit | Name | Read/Write | Description |
|-----|----------|------------|--|
| 0 | Not Used | R/W | This bit is not used |
| 1 | Z1_SS | R/W | Setting this bit includes the Z1 touch-pressure measurement (X+ input) in a slave mode sequence |
| 2 | TEMP2_SS | R/W | Setting this bit includes a temperature measurement using differential conversion in a slave mode sequence |
| 3 | TEMP1_SS | R/W | Setting this bit includes a temperature measurement using single-ended conversion in a slave mode sequence |
| 4 | BAT2_SS | R/W | Setting this bit includes measurement of Battery Monitor Input 2 in a slave mode sequence |
| 5 | BAT1_SS | R/W | Setting this bit includes measurement of Battery Monitor Input 1 in a slave mode sequence |
| 6 | AUX3_SS | R/W | Setting this bit includes measurement of Auxiliary Input 3 in a slave mode sequence |
| 7 | AUX2_SS | R/W | Setting this bit includes measurement of Auxiliary Input 2 in a slave mode sequence |
| 8 | AUX1_SS | R/W | Setting this bit includes measurement of Auxiliary Input 1 in a slave mode sequence |
| 9 | Z2_SS | R/W | Setting this bit includes the Z2 touch-pressure measurement (Y- input) in a slave mode sequence |
| 10 | XPOS_SS | R/W | Setting this bit includes measurement of the X position (Y+ input) in a slave mode sequence |
| 11 | YPOS_SS | R/W | Setting this bit includes measurement of the Y position (X+ input) in a slave mode sequence |

Register Name: Sequencer Register 1

Write Address: 1101; Read Address: 01101; Default Value: 0x000; Type: Read/Write.

Table 20.

| Bit | Name | Read/Write | Description |
|-----|----------|------------|---|
| 0 | Not Used | R/W | This bit is not used |
| 1 | Z1_MS | R/W | Setting this bit includes the Z1 touch-pressure measurement (X+ input) in a master mode sequence |
| 2 | TEMP2_MS | R/W | Setting this bit includes a temperature measurement using differential conversion in a master mode sequence |
| 3 | TEMP1_MS | R/W | Setting this bit includes a temperature measurement using single-ended conversion in a master mode sequence |
| 4 | BAT2_MS | R/W | Setting this bit includes measurement of Battery Monitor Input 2 in a master mode sequence |
| 5 | BAT1_MS | R/W | Setting this bit includes measurement of Battery Monitor Input 1 in a master mode sequence |
| 6 | AUX3_MS | R/W | Setting this bit includes measurement of Auxiliary Input 3 in a master mode sequence |
| 7 | AUX2_MS | R/W | Setting this bit includes measurement of Auxiliary Input 2 in a master mode sequence |
| 8 | AUX1_MS | R/W | Setting this bit includes measurement of Auxiliary Input 1 in a master mode sequence |
| 9 | Z2_MS | R/W | Setting this bit includes the Z2 touch-pressure measurement (Y- input) in a master mode sequence |
| 10 | XPOS_MS | R/W | Setting this bit includes measurement of the X position (Y+ input) in a master mode sequence |
| 11 | YPOS_MS | R/W | Setting this bit includes measurement of the Y position (X+ input) in a master mode sequence |

Register Name: DAC Register

Write Address: 1110; Read Address: 01110; Default Value: 0x000; Type: Read/Write.

Table 21.

| Bit | Name | Read/Write | Description |
|-----|----------|------------|---|
| 0 | RANGE | R/W | Output range of the DAC in voltage mode 0 = 0 to $V_{CC}/2$ 1 = 0 to V_{CC} |
| 1 | Not Used | R/W | This bit is not used |
| 2 | V/I | R/W | Voltage output and current output 0 = voltage 1 = current |
| 3 | PD | R/W | DAC power-down 0 = DAC on 1 = DAC powered down |
| 4 | DAC0 | | LSB of DAC data |
| 5 | DAC1 | | Bit 1 of DAC data |
| 6 | DAC2 | | Bit 2 of DAC data |
| 7 | DAC3 | | Bit 3 of DAC data |
| 8 | DAC4 | | Bit 4 of DAC data |
| 9 | DAC5 | | Bit 5 of DAC data |
| 10 | DAC6 | | Bit 6 of DAC data |
| 11 | DAC7 | | MSB of DAC data |

Register Name: Y Position

Write Address: N/A; Read Address: 10000;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at the X+ input with Y layer excited (Y position measurement).

Register Name: X Position

Write Address: N/A; Read Address: 10001;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at the Y+ input with X layer excited (X position measurement).

Register Name: Z2

Write Address: N/A; Read Address: 10010;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at the Y- input with excitation voltage applied to Y+ and X- (used for touch-pressure calculation).

Register Name: AUX1

Write Address: N/A; Read Address: 10011;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at Auxiliary Input 1.

Register Name: AUX2

Write Address: N/A; Read Address: 10100;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at Auxiliary Input 2.

Register Name: AUX3

Write Address: N/A; Read Address: 10101;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at Auxiliary Input 3.

Register Name: BAT1

Write Address: N/A; Read Address: 10110;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at Battery Monitor Input 1.

Register Name: BAT2

Write Address: N/A; Read Address: 10111;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of the measurement at Battery Monitor Input 2.

Register Name: TEMP1

Write Address: N/A; Read Address: 11000;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of a temperature measurement using single-ended conversion.

Register Name: TEMP2

Write Address: N/A; Read Address: 11001;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of a temperature measurement using a differential conversion.

Register Name: Z1

Write Address: N/A; Read Address: 11010;
Default Value: 0x000; Type: Read Only.

This register contains the 12-bit result of a measurement at the X+ input with excitation voltage applied to Y+ and X- (used for touch-pressure calculation).

GPIO REGISTERS

GPIO registers are written to using an extended 8-bit address. The first four bits of the data-word are always 1111b to access the extended writing map. The next four bits are the register address. This leaves 8 bits for the GPIO data.

GPIO registers are read like all other registers, by writing a 5-bit address to Control Register 1, then reading DOUT.

See the GPIO Configuration section for information on configuring the GPIOs.

Register Name: GPIO Control Register 1

Write Address: [1111] 0000; Read Address: 11011; Default Value: 0x000; Type: Read/Write.

Table 22.

| Bit | Name | Read/Write | Description |
|-----|------------|------------|--|
| 0 | GPIO2_ALEN | R/W | If this bit is 1, GPIO2 is an interrupt source for the ALERT output; clearing this bit masks out GPIO2 as an interrupt source for the ALERT output |
| 1 | GPIO2_DIR | R/W | This bit sets the direction of GPIO2 0 = output 1 = input |
| 2 | GPIO2_POL | R/W | This bit determines if GPIO2 is active high or low 0 = active low 1 = active high |
| 3 | GPIO2_EN | R/W | This bit selects the function of AUX2/GPIO2 0 = AUX2 1 = GPIO2 |
| 4 | GPIO1_ALEN | R/W | If this bit is 1, GPIO1 is an interrupt source for the ALERT output; clearing this bit masks out GPIO1 as an interrupt source for the ALERT output |
| 5 | GPIO1_DIR | R/W | This bit sets the direction of GPIO1 0 = output 1 = input |
| 6 | GPIO1_POL | R/W | This bit determines if GPIO1 is active high or low 0 = active low 1 = active high |
| 7 | GPIO1_EN | R/W | This bit selects the function of AUX1/GPIO1 0 = AUX1 1 = GPIO1 |

Register Name: GPIO Control Register 2

Write Address: [1111] 0001; Read Address: 11100; Default Value: 0x000; Type: Read/Write.

Table 23.

| Bit | Name | Read/Write | Description |
|-----|------------|------------|--|
| 0 | GPIO4_ALEN | R/W | If this bit is 1, GPIO4 is an interrupt source for the $\overline{\text{ALERT}}$ output; clearing this bit masks out GPIO3 as an interrupt source for the $\overline{\text{ALERT}}$ output |
| 1 | GPIO4_DIR | R/W | This bit sets the direction of GPIO4 0 = output 1 = input |
| 2 | GPIO4_POL | R/W | This bit determines if GPIO4 is active high or low 0 = active low 1 = active high |
| 3 | Not Used | | This bit is not used |
| 4 | GPIO3_ALEN | R/W | If this bit is 1, GPIO3 is an interrupt source for the $\overline{\text{ALERT}}$ output; clearing this bit masks out GPIO4 as an interrupt source for the $\overline{\text{ALERT}}$ output |
| 5 | GPIO3_DIR | R/W | This bit sets the direction of GPIO3 0 = output 1 = input |
| 6 | GPIO3_POL | R/W | This bit determines if GPIO3 is active high or low 0 = active low 1 = active high |
| 7 | GPIO3_EN | R/W | This bit selects the function of AUX3/GPIO3 0 = AUX3 1 = GPIO3 |

Register Name: GPIO Data Register

Write Address: [1111] 0010; Read Address: 11101; Default Value: 0x000; Type: Read/Write.

Table 24.

| Bit | Name | Read/Write | Description |
|-----|-----------|------------|----------------------|
| 0 | Not used | | This bit is not used |
| 1 | Not used | | This bit is not used |
| 2 | Not used | | This bit is not used |
| 3 | Not used | | This bit is not used |
| 4 | GPIO4_DAT | R/W | GPIO4 data bit |
| 5 | GPIO3_DAT | R/W | GPIO3 data bit |
| 6 | GPIO2_DAT | R/W | GPIO2 data bit |
| 7 | GPIO1_DAT | R/W | GPIO1 data bit |
