ANALOG High Precision, Wideband RMS-to-DC Converter

## FEATURES

```
High accuracy
    0.02% max nonlinearity, 0 V to 2 V rms input
    0.10% additional error to crest factor of }
Wide bandwidth
    8 MHz at 2 V rms input
    600 kHz at 100 mV rms
Computes
    True rms
    Square
    Mean square
    Absolute value
dB output ( }60\textrm{dB}\mathrm{ range)
Chip select/power-down feature allows
    Analog three-state operation
    Quiescent current reduction from 2.2 mA to 350 \muA
14-lead SBDIP, 14-lead low cost CERDIP, and 16-lead SOIC_W
GENERAL DESCRIPTION
```

The AD637 is a complete high accuracy, monolithic rms-to-dc converter that computes the true rms value of any complex waveform. It offers performance that is unprecedented in integrated circuit rms-to-dc converters and comparable to discrete and modular techniques in accuracy, bandwidth, and dynamic range. A crest factor compensation scheme in the AD637 permits measurements of signals with crest factors of up to 10 with less than $1 \%$ additional error. The circuit's wide bandwidth permits the measurement of signals up to 600 kHz with inputs of 200 mV rms and up to 8 MHz when the input levels are above 1 V rms.

As with previous monolithic rms converters from ADI, the AD637 has an auxiliary dB output available to the user. The logarithm of the rms output signal is brought out to a separate pin, allowing direct dB measurement with a useful range of 60 dB. An externally programmed reference current allows the user to select the 0 dB reference voltage to correspond to any level between 0.1 V and 2.0 V rms.

A chip select connection on the AD637 permits the user to decrease the supply current from 2.2 mA to $350 \mu \mathrm{~A}$ during periods when the rms function is not in use. This feature facilitates the addition of precision rms measurement to remote or hand-held applications where minimum power consumption is critical. In addition, when the AD637 is powered down, the output goes to a high impedance state. This allows several AD637s to be tied together to form a wideband true rms multiplexer.

FUNCTIONAL BLOCK DIAGRAM

Figure 1. SBDIP (D-14) and CERDIP (Q-14) Packages

The input circuitry of the AD637 is protected from overload voltages that are in excess of the supply levels. The inputs are not damaged by input signals if the supply voltages are lost.
The AD637 is available in Accuracy Grades J and K for commercial temperature range ( $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$ ) applications; Accuracy Grades A and B for industrial range $\left(-40^{\circ} \mathrm{C}\right.$ to $\left.+85^{\circ} \mathrm{C}\right)$ applications; and Accuracy Grade $S$ rated over the $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ temperature range. All versions are available in hermetically sealed, 14-lead SBDIP, 14-lead CERDIP, and 16-lead SOIC packages.
The AD637 computes the true root-mean-square, mean-square, or absolute value of any complex ac (or ac plus dc) input waveform and gives an equivalent dc output voltage. The true rms value of a waveform is more useful than an average rectified signal since it relates directly to the power of the signal. The rms value of a statistical signal is also related to the standard deviation of the signal.

The AD637 is laser wafer trimmed to achieve rated performance without external trimming. The only external component required is a capacitor that sets the averaging time period. The value of this capacitor also determines low frequency accuracy, ripple level, and settling time.
The on-chip buffer amplifier can be used either as an input buffer or in an active filter configuration. The filter can be used to reduce the amount of ac ripple, thereby increasing accuracy.

## SPECIFICATIONS ${ }^{1}$

At $25^{\circ} \mathrm{C}$, and $\pm 15 \mathrm{~V}$ dc unless otherwise noted.
Table 1.

## AD637

${ }^{1}$ Specifications shown in bold are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.
${ }^{2}$ Accuracy specified 0 V rms to 7 V rms dc with AD637 connected as shown in Figure 5.
${ }^{3}$ Nonlinearity is defined as the maximum deviation from the straight line connecting the readings at 10 mV and 2 V .
${ }^{4}$ Error vs. crest factor is specified as additional error for 1 V rms.
${ }^{5}$ Input voltages are expressed in volts rms. Percent is in \% of reading.
${ }^{6}$ With external $2 \mathrm{k} \Omega$ pull-down resistor tied to $-\mathrm{V}_{\mathrm{s}}$.

## AD637

## ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
| :--- | :--- |
| ESD Rating | 500 V |
| Supply Voltage | $\pm 18 \mathrm{~V} \mathrm{dc}$ |
| Internal Quiescent Power Dissipation | 108 mW |
| Output Short-Circuit Duration | Indefinite |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Lead Temperature Range (Soldering 10 secs) | $300^{\circ} \mathrm{C}$ |
| Rated Operating Temperature Range |  |
| $\quad$ AD637J, AD637K | $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$ |
| AD637A, AD637B | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| AD637S, 5962-8963701CA | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## AD637

## FUNCTIONAL DESCRIPTION

Figure 4. Simplified Schematic

The AD637 embodies an implicit solution of the rms equation that overcomes the inherent limitations of straightforward rms computation. The actual computation performed by the AD637 follows the equation

$$
V r m s=A v g\left[\frac{V_{\mathrm{IN}^{2}}}{V r m s}\right]
$$

Figure 4 is a simplified schematic of the AD637, subdivided into four major sections: absolute value circuit (active rectifier), squarer/divider, filter circuit, and buffer amplifier. The input voltage $\mathrm{V}_{\text {IN }}$, which can be ac or dc , is converted to a unipolar current $I_{1}$ by the active rectifier A1, A2. $I_{1}$ drives one input of the squarer/divider, which has the transfer function

$$
I_{4}=\frac{I_{1}^{2}}{I_{3}}
$$

The output current of the squarer/divider $\mathrm{I}_{4}$ drives A4, which forms a low-pass filter with the external averaging capacitor. If the RC time constant of the filter is much greater than the longest period of the input signal, A4's output is proportional to the average of $\mathrm{I}_{4}$. The output of this filter amplifier is used by A3 to provide the denominator current $\mathrm{I}_{3}$, which equals $\operatorname{Avg} \mathrm{I}_{4}$ and is returned to the squarer/divider to complete the implicit rms computation

$$
I_{4}=\operatorname{Avg}\left[\frac{I_{1}^{2}}{I_{4}}\right]=I_{1} \mathrm{rms}
$$

and

$$
V_{\text {OUT }}=V_{I N} r m s
$$

If the averaging capacitor is omitted, the AD637 computes the absolute value of the input signal. A nominal 5 pF capacitor should be used to ensure stability. The circuit operates identically to that of the rms configuration except that $\mathrm{I}_{3}$ is now equal to $\mathrm{I}_{4}$, giving

$$
\begin{aligned}
& I_{4}=\frac{I_{1}^{2}}{I_{4}} \\
& I_{4}=\left|I_{1}\right|
\end{aligned}
$$

The denominator current can also be supplied externally by providing a reference voltage, $\mathrm{V}_{\text {ref }}$, to Pin 6 . The circuit operates identically to the rms case except that $\mathrm{I}_{3}$ is now proportional to Vref. Therefore,

$$
I_{4}=A v g \frac{I_{1}^{2}}{I_{3}}
$$

and

$$
V_{O}=\frac{V_{I N}^{2}}{V_{D E N}}
$$

This is the mean square of the input signal.

## STANDARD CONNECTION

The AD637 is simple to connect for a majority of rms measurements. In the standard rms connection shown in Figure 5, only a single external capacitor is required to set the averaging time constant. In this configuration, the AD637 computes the true rms of any input signal. An averaging error, the magnitude of which is dependent on the value of the averaging capacitor, is present at low frequencies. For example, if the filter capacitor, $\mathrm{C}_{\mathrm{AV}}$, is $4 \mu \mathrm{~F}$, the error is $0.1 \%$ at 10 Hz and increases to $1 \%$ at 3 Hz . To measure ac signals, the AD637 can be ac-coupled through the addition of a nonpolar capacitor in series with the input, as shown in Figure 5.

Figure 5. Standard RMS Connection
The performance of the AD637 is tolerant of minor variations in the power supply voltages; however, if the supplies used exhibit a considerable amount of high frequency ripple, it is advisable to bypass both supplies to ground through a $0.1 \mu \mathrm{~F}$ ceramic disc capacitor placed as close to the device as possible.
The output signal range of the AD637 is a function of the supply voltages, as shown in Figure 6. The output signal can be used buffered or nonbuffered, depending on the characteristics of the load. If no buffer is needed, tie the buffer input (Pin 1) to common. The output of the AD637 is capable of driving 5 mA into a $2 \mathrm{k} \Omega$ load without degrading the accuracy of the device.

Figure 6. AD637 Maximum Vout Vs. Supply Voltage

## CHIP SELECT

The AD637 includes a chip select feature that allows the user to decrease the quiescent current of the device from 2.2 mA to $350 \mu \mathrm{~A}$. This is done by driving the CS, Pin 5 , to below 0.2 V dc. Under these conditions, the output goes into a high impedance state. In addition to lowering power consumption, this feature permits bussing the outputs of a number of AD637s to form a wide bandwidth rms multiplexer. If the chip select is not being used, Pin 5 should be tied high.

## OPTIONAL TRIMS FOR HIGH ACCURACY

The AD637 includes provisions for trimming out output offset and scale factor errors resulting in significant reduction in the maximum total error, as shown in Figure 7. The residual error is due to a nontrimmable input offset in the absolute value circuit and the irreducible nonlinearity of the device.
Referring to Figure 8, the trimming process follows:

- Offset trim: Ground the input signal, Vin, and adjust R1 to give 0 V output from Pin 9. Alternatively, R1 can be adjusted to give the correct output with the lowest expected value of $\mathrm{V}_{\mathrm{IN}}$.
- Scale factor trim: Resistor R4 is inserted in series with the input to lower the range of the scale factor. Connect the desired full-scale input to $\mathrm{V}_{\mathrm{IN}}$, using either a dc or a calibrated ac signal, and trim R3 to give the correct output at Pin 9, that is, 1 V dc should give 1.000 V dc output. Of course, a 2 V p-p sine wave should give 0.707 V dc output. Remaining errors are due to the nonlinearity.

## AD637

Table 5. Practical Values of $\mathrm{C}_{\mathrm{Av}}$ and C2 for Various Input Waveforms

## FREQUENCY RESPONSE

The frequency response of the AD637 at various signal levels is shown in Figure 15. The dashed lines show the upper frequency limits for $1 \%, 10 \%$, and $\pm 3 \mathrm{~dB}$ of additional error. For example, note that for $1 \%$ additional error with a 2 V rms input, the highest frequency allowable is 200 kHz . A 200 mV signal can be measured with $1 \%$ error at signal frequencies up to 100 kHz .

To take full advantage of the wide bandwidth of the AD637, care must be taken in the selection of the input buffer amplifier. To ensure that the input signal is accurately presented to the converter, the input buffer must have a -3 dB bandwidth that is wider than that of the AD637. Note the importance of slew rate in this application. For example, the minimum slew rate required for a $1 \mathrm{~V} \mathrm{rms}, 5 \mathrm{MHz}$, sine wave input signal is $44 \mathrm{~V} / \mu \mathrm{s}$. The user is cautioned that this is the minimum rising or falling slew rate and that care must be exercised in the selection of the buffer amplifier, since some amplifiers exhibit a two-to-one difference between rising and falling slew rates. The AD845 is recommended as a precision input buffer.

Figure 15. Frequency Response

## AC MEASUREMENT ACCURACY AND CREST FACTOR

Crest factor is often overlooked in determining the accuracy of an ac measurement. Crest factor is defined as the ratio of the peak signal amplitude to the rms value of the signal ( $\mathrm{CF}=\mathrm{Vp} / \mathrm{Vrms}$ ). Most common waveforms, such as sine and triangle waves, have relatively low crest factors ( $\leq 2$ ). Waveforms that resemble low duty cycle pulse trains, such as those occurring in switching power supplies and SCR circuits, have high crest factors. For example, a rectangular pulse train with a $1 \%$ duty cycle has a crest factor of $10(\mathrm{CF}=1 \sqrt{\eta})$.

Figure 16. AD637 Error vs. Pulse Width Rectangular Pulse
Figure 17 is a curve of additional reading error for the AD637 for a 1 V rms input signal with crest factors from 1 to 11 . A rectangular pulse train (pulse width $100 \mu \mathrm{~s}$ ) was used for this test because it is the worst-case waveform for rms measurement (all the energy is contained in the peaks). The duty cycle and peak amplitude were varied to produce crest factors from 1 to 10 while maintaining a constant 1 V rms input amplitude.

Figure 17. Additional Error vs. Crest Factor

Figure 18. Error vs. RMS Input Level for Three Common Crest Factors

## CONNECTION FOR DB OUTPUT

Another feature of the AD637 is the logarithmic, or decibel, output. The internal circuit that computes dB works well over a 60 dB range. Figure 19 shows the dB measurement connection. The user selects the 0 dB level by setting R1 for the proper 0 dB reference current, which is set to exactly cancel the log output current from the squarer/divider circuit at the desired 0 dB point. The external op amp is used to provide a more convenient scale and to allow compensation of the $+0.33 \% /{ }^{\circ} \mathrm{C}$ temperature drift of the dB circuit. The special TC resistor R3 is available from Precision Resistor Inc., Largo, Fla (Model PT146).

## AD637

Figure 19. $d B$ Connection

Figure 20. AD637 as a Low Frequency RMS Converter

## dB CALIBRATION

Refer to Figure 19:

- Set VIN $=1.00 \mathrm{~V}$ dc or 1.00 V rms
- Adjust R1 for 0 dB out $=0.00 \mathrm{~V}$
- Set VIN $=0.1 \mathrm{~V}$ dc or 0.10 V rms
- Adjust R2 for dB out $=-2.00 \mathrm{~V}$

Any other dB reference can be used by setting $\mathrm{V}_{\text {IN }}$ and R1 accordingly.

## LOW FREQUENCY MEASUREMENTS

If the frequencies of the signals to be measured are below 10 Hz , the value of the averaging capacitor required to deliver even $1 \%$ averaging error in the standard rms connection becomes extremely large. Figure 20 shows an alternative method of obtaining low frequency rms measurements. The averaging time constant is determined by the product of R and $\mathrm{C}_{\mathrm{AV} 1}$, in this circuit $0.5 \mathrm{~s} / \mu \mathrm{F}$ of $\mathrm{C}_{\mathrm{AV}}$. This circuit permits a 20:1 reduction in the value of the averaging capacitor, permitting the use of high quality tantalum capacitors. It is suggested that the two-pole, Sallen-Key filter shown in Figure 20 be used to obtain a low ripple level and minimize the value of the averaging capacitor.

If the frequency of interest is below 1 Hz , or if the value of the averaging capacitor is still too large, the 20:1 ratio can be increased. This is accomplished by increasing the value of R. If this is done, it is suggested that a low input current, low offset voltage amplifier, such as the AD548, be used instead of the internal buffer amplifier. This is necessary to minimize the offset error introduced by the combination of amplifier input currents and the larger resistance.

## VECTOR SUMMATION

Vector summation can be accomplished through the use of two AD637s, as shown in Figure 21. Here the averaging capacitors are omitted (nominal 100 pF capacitors are used to ensure stability of the filter amplifier), and the outputs are summed as shown. The output of the circuit is

$$
V_{O}=\sqrt{V_{X}^{2}+V_{Y}^{2}}
$$

This concept can be expanded to include additional terms by feeding the signal from Pin 9 of each additional AD637 through a $10 \mathrm{k} \Omega$ resistor to the summing junction of the AD711 and tying all of the denominator inputs (Pin 6) together.
If $\mathrm{C}_{\mathrm{AV}}$ is added to IC1 in this configuration, the output is

$$
\sqrt{\overline{V_{X}^{2}}+V_{Y}{ }^{2}}
$$

If the averaging capacitor is included on both IC1 and IC2, the output is

$$
\sqrt{\overline{V_{X}^{2}}+\overline{V_{Y}^{2}}}
$$

This circuit has a dynamic range of 10 V to 10 mV and is limited only by the 0.5 mV offset voltage of the AD637. The useful bandwidth is 100 kHz .
