

## 1.3 MP CMOS Image Sensor

**Table 1. Key Performance Parameters**

Parameter	Typical Value
Active Pixels	1280 (H) x 1024 (V)
Pixel Size	6.7 $\mu\text{m}$ x 6.7 $\mu\text{m}$
Optical format	2/3 inch
Shutter Type	Snapshot (Global) Shutter Rolling Shutter
Maximum Data Rate / Master Clock	40 MPS / 40 MHz
Frame rate	27 fps (1280 x 1024) 106 fps (640 x 480)
ADC resolution	10-bit, on-chip
Sensitivity (@ 650 nm)	715 V.m <sup>2</sup> /W.s 8.40 V/lux.s
S/N Ratio	64 dB
Full Well Charge	62.500 e <sup>-</sup>
Temporal Noise	40 e <sup>-</sup>
Dark current	7.22 mV/s
High Dynamic Range	Multiple Slope
Supply Voltage	Analog: 3.0V–4.5V Digital: 3.3V I/O: 3.3V
Power consumption	175 mW
Operating temperature	-30°C to +65°C
Color Filter Array	Mono RGB Bayer Pattern
Packaging	84-pins LCC

### Description

The IBIS5-B-1300 is a solid state CMOS image sensor that integrates the functionality of complete analog image acquisition, digitizer and digital signal processing system on a single chip. This 1.3-mega pixel (1280 x 1024) CMOS active pixel sensor dedicated to industrial vision applications features both rolling and snapshot (or global) shutter. Full frame readout time is 36 ms (max. 27.5 fps), and readout speed can be boosted by windowed region of interest (ROI) readout. High dynamic range scenes can be captured using the double and multiples slope functionality. The sensor is available in a Monochrome version or Bayer (RGB) patterned color filter array.

User programmable row and column start/stop positions allow windowing down to a 2x1 pixel window for digital zoom. Sub sampling or viewfinder mode reduces resolution while maintaining the constant field of view and an increased frame rate. The analog video output of the pixel array is processed by an on-chip analog signal pipeline. Double Sampling (DS) eliminates the fixed pattern noise. The programmable gain and offset amplifier maps the signal swing to the ADC input range. A 10-bit ADC converts the analog data to a 10-bit digital word stream. The sensor uses an 2-wire, I<sup>2</sup>C™-compatible, interface, a 3-wire Serial-Parallel (SPI) interface, or a 16-bit parallel interface. It operates with a 3.3V power supply and requires only one master clock for operation up to 40 MHz. It is housed in an 84-pin ceramic LCC package.

### Applications

- Machine vision
- Inspection
- Robotics
- Traffic monitoring

## Architecture and Operation

In this part the most important blocks of the sensor are described in more detail.

### Floor Plan

**Figure 1. Block Diagram of the IBIS5-B-1300 Image Sensor**

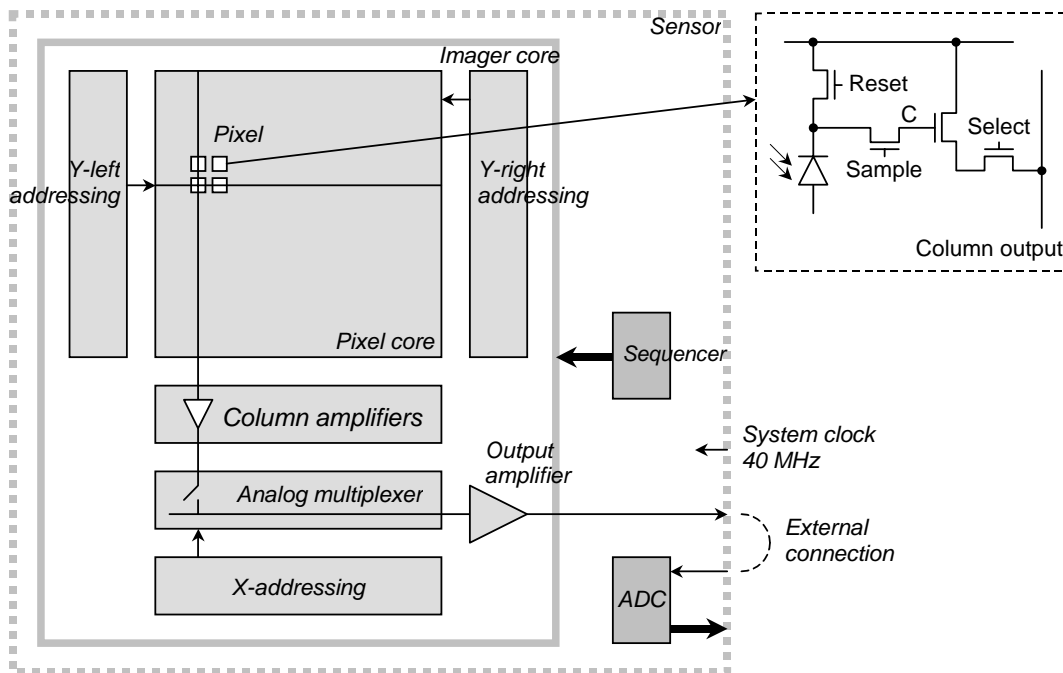

Figure 1 shows the architecture of the IBIS5-B-1300 image sensor. It consists basically of a pixel array, one X- and two Y-addressing registers for the readout in X- and Y-direction, column amplifiers that correct for the fixed pattern noise, an analog multiplexer, and an analog output amplifier.

The left Y-addressing register is used for readout operation. The right Y-addressing register is used for reset of pixel rows. In multiple slope synchronous shutter mode, the right Y-addressing register resets the whole pixel core with a lowered reset voltage. In rolling curtain shutter mode, the right Y-addressing register is used for the reset pointer in single and double slope operation to reset 1 pixel row.

Most of the signals for the image core are generated by the on-chip sequencer. Some basic signals (like start/stop integration, line and frame sync signals, etc.) have to be generated externally.

A 10-bit ADC is implemented on chip but electrically isolated from the image core. The analog pixel output has to be routed to the analog ADC input on the outside.

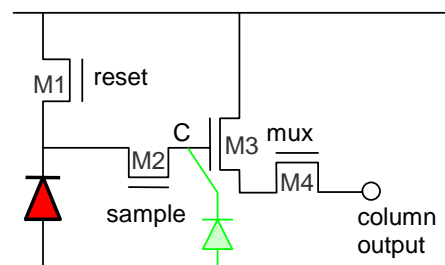

### Pixel

The pixel architecture and the color filter array are described below.

### Architecture

The pixel architecture used in the IBIS5-B-1300 is a 4-transistor pixel as shown in Figure 2. The pixel has been implemented using the high fill factor technique as patented by Cypress (US patent No. 6,225,670 and others). The 4T-pixel features a snapshot shutter but can also emulate the 3T-pixel by continuously closing sampling switch M2. Using M4 as a global sample transistor for all pixels enables the snapshot shutter mode. Due to this pixel architecture, integration during read out is not possible in synchronous shutter mode.

**Figure 2. Architecture of the 4T-pixel**

**Color Filter Array**

The IBIS5-B-1300 can also be processed with a Bayer RGB color pattern. Pixel (0,0) has a green filter and is situated on a green-blue row. Green1 and green2 have a slightly different spectral response due to cross talk from neighboring pixels. Green1 pixels are located on a blue-green row, green2 pixels are located on a green-red row. Figure 4 below shows the response of the color filter array as function of the wavelength. Note that this response curve includes the optical cross talk of the pixels.

**Figure 3. Color Filter Arrangement on the Pixels**

**Frame Rate**

The pixel rate for this sensor is high enough to support a frame rate of >100 Hz for a window size of 640 x 480 pixels (VGA format). Taking into account a row blanking time of 3.5 ms (as

baseline, see also “Internal Clock Granularities (bits 4, 5, 6 and 7)” on page 13), this requires a minimum pixel rate of nearly 40 MHz. The final bandwidth of the column amplifiers, output stage, and others is determined by external bias resistors. With a nominal pixel rate of 40 MHz, a full frame rate of a little more than 27 frames per second is obtained.

The frame period of the IBIS5-B-1300 sensor depends on the shutter type.

**Rolling Shutter**

=> Frame period = (Nr. Lines \* (RBT + pixel period \* Nr. Pixels))

with:

Nr. Lines: Number of Lines read out each frame (Y).

Nr. Pixels: Number of pixels read out each line (X).

RBT: Row Blanking Time = 3.5 ms (typical).

Pixel period: 1/40 MHz = 25 ns.

**Example** Read out time of the full resolution at nominal speed (40-MHz pixel rate):

=> Frame period = (1024 \* (3.5 ms + 25 ns \* 1280)) = 36.4 ms  
=> 27.5 fps.

**Snapshot shutter**

=> Frame period = Tint + Tread out

= Tint + (Nr. Lines \* (RBT + pixel period \* Nr. Pixels))

with:

Tint: Integration (exposure) time.

Nr. Lines: Number of Lines read out each frame (Y).

Nr. Pixels: Number of pixels read out each line (X).

**Figure 4. Color Filter Response**

RBT: Row Blanking Time = 3.5 ms (typical).

Pixel period: 1/40 MHz = 25 ns.

**Example** Read out time of the full resolution at nominal speed (40 MHz pixel rate) with an integration time of 1 ms:

=> Frame period = 1 ms + (1024 \* (3.5 ms + 25 ns \* 1280)) = 37.4 ms => 26.8 fps.

*Region-Of-Interest (ROI) Read Out*

Windowing can easily be achieved by uploading the starting point of the x- and y-shift registers in the sensor registers using the various interfaces. This downloaded starting point initiates the shift register in the x- and y-direction triggered by the Y\_START (initiates the Y-shift register) and the Y\_CLK (initiates the X-shift register) pulse. The minimum step size for the x-address is 2 (only even start addresses can be chosen) and 1 for the Y-address (every line can be addressed). The frame rate increases almost linearly when fewer pixels are read out. Table 2 gives an overview of the achievable frame rates (in rolling shutter mode) with various ROI dimensions.

**Table 2. Frame Rate vs. Resolution**

Image Resolution (X*Y)	Frame Rate [frames/s]	Frame Readout Time [ms]	Comment
1280 x 1024	27	36	Full resolution.
640 x 480	100	10	ROI read out.
100 x 100	1657	0.6	ROI read out.

**Image Core Operation**

*Image Core Operation and Signalling*

Figure 5 is a functional representation of the image core without sub-sampling and column/row swapping circuits. Most of the involved signals are not available from the outside because they are generated by the X-sequencer and SS-sequencer blocks.

The integration of the pixels is controlled by internal signals such as reset, sample, hold are generated by the on-chip SS-sequencer that is controlled with the external signals SS\_START and SS\_STOP. Reading out the pixel array starts by applying a Y\_START together with a Y\_CLOCK signal; internally this is followed by a calibration sequence to calibrate the output amplifiers (during the row blanking time); signals necessary to do this calibration are generated by the on-chip X-sequencer. This calibration sequence takes typically 3.5 μs and is necessary to remove Fixed Pattern Noise of the pixels and of the column amplifiers themselves by means of a Double Sampling technique. After the row blanking time the pixels are fed to the output amplifier. The pixel rate is equal to the SYS\_CLOCK frequency.

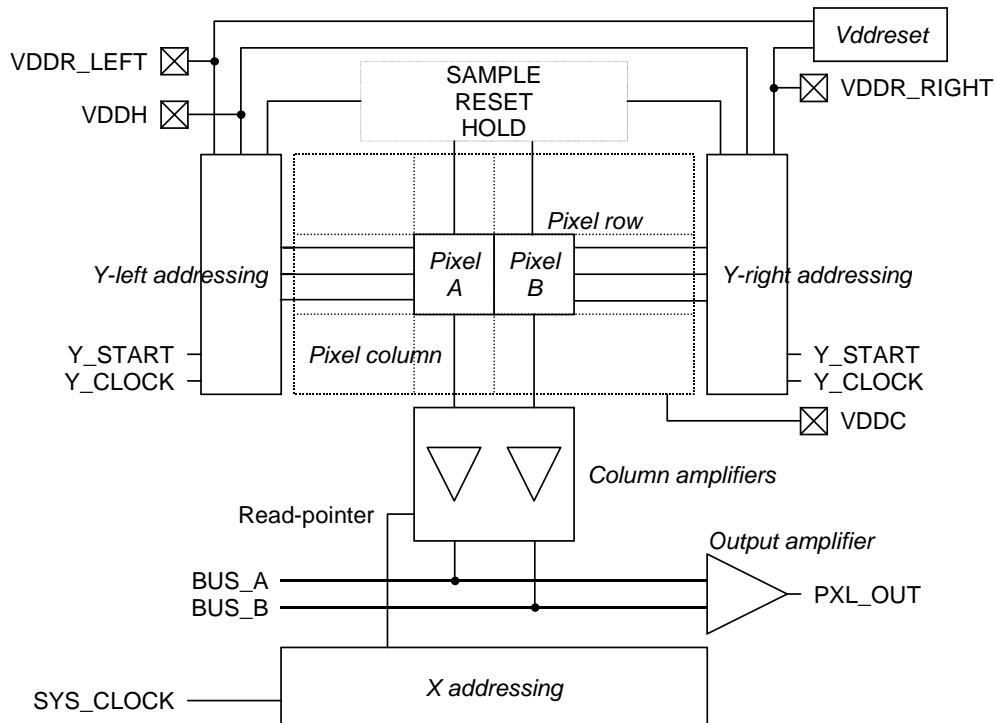

*Image Core Supply Considerations*

The image sensor has several supply voltages:

VDDH is the voltage that controls the sample switches and must always be the highest voltage that is applied to the chip.

The VDDR\_LEFT voltage is the highest (nominal) reset voltage of the pixel core.

**Figure 5. Image Core**

The VDDR\_RIGHT voltage is generated from the VDDR\_LEFT voltage using a circuit that can be programmed with the KNEEPOINT\_LSB/MSB bits in the sequencer register (see also “Pixel Reset Knee-point for Multiple Slope Operation (bits 8, 9, and 10),” on page 14). By setting the VDDR\_RIGHT\_EXT bit in the SEQUENCER register, the VDDR\_RIGHT pin can be disconnected from the circuit and an external voltage can be applied to supply the multiple slope reset voltage. When no external voltage is applied (recommended) the VDDR\_RIGHT pin should be connected to a capacitor (recommended value = 1µF). VDDC is the supply of the pixel core. VDDA is the analog supply of the image core and periphery. VDDD is the digital supply of the image core and periphery.

Note that the IBIS5-B-1300 image sensor has no power rejection circuitry on-chip. As a consequence all variations on the analog supply voltages can contribute to random variations (noise) on the analog pixel signal, which is seen as random noise in the image. During the camera design precautions have to be taken to supply the sensor with very stable supply voltages to avoid this additional noise. Especially the analog supplies of the pixel array (VDDR\_LEFT, VDDH and VDDC) are vulnerable for this.

#### Snapshot Shutter Supply Considerations

When using the IBIS5-B-1300 sensor in snapshot shutter mode only the recommended supply voltage settings are listed below in Table 3.

**Table 3. Snapshot Shutter Recommended Supply Settings**

Parameter	Description	Typ.	Unit
VDDH	Voltage on HOLD switches.	+4.5	V
VDDR_LEFT	Highest reset voltage.	+4.5	V
VDDC	Pixel core voltage.	+3.3	V
VDDA	Analog supply voltage of the image core.	+3.3	V
VDDD	Digital supply voltage of the image core.	+3.3	V
GND_A	Analog ground.	0	V
GND_D	Digital ground.	0	V
GND_AB	Anti-blooming ground.	0	V

**Table 5. Overview of Bias Signals**

Signal	Comment	Related module	DC-level
DEC_CMD	Connect to VDDA with R = 50 kΩ and decouple to GND_A with C = 100 nF.	Decoder stage.	1.0V
DAC_VHIGH	Connect to VDDA with R = 0Ω.	High level of DAC.	3.3V
DAC_VLOW	Connect to GND_A with R = 0Ω.	Low level of DAC.	0.0V
AMP_CMD	Connect to VDDA with R = 50 kΩ and decouple to GND_A with C = 100 nF.	Output amplifier stage.	1.2V
COL_CMD	Connect to VDDA with R = 50 kΩ and decouple to GND_A with C = 100 nF.	Columns amplifiers stage.	1.0V
PC_CMD	Connect to VDDA with R = 25 kΩ and decouple to GND_A with C = 100 nF.	Pre-charge of column busses.	1.1V
ADC_CMD	Connect to VDDA with R = 50 kΩ and decouple to GND_A with C = 100 nF.	Analog stage of ADC.	1.0V
ADC_VHIGH	Connect to VDDA with R = 360Ω and decouple to GND_A with C = 100 nF.	High level of ADC.	2.7V
ADC_VLOW	Connect to GND_A with R = 1200Ω and decouple to GND_A with C = 100 nF.	Low level of ADC.	1.8V

#### Dual Shutter Supply Considerations

With the supply settings listed in Table 3 some fixed column non-uniformities (FPN) can be seen when operating in rolling shutter mode. If a dual shutter mode (both rolling and snapshot shutter) is required during operation one needs to apply the supply settings listed in Table 4 below to achieve the best possible image quality.

**Table 4. Dual Shutter Recommended Supply Settings**

Parameter	Description	Typ.	Unit
VDDH	Voltage on HOLD switches.	+4.5	V
VDDR_LEFT	Highest reset voltage.	+4.5	V
VDDC	Pixel core voltage.	+3.0	V
VDDA	Analog supply voltage of the image core.	+3.3	V
VDDD	Digital supply voltage of the image core.	+3.3	V
GND_A	Analog ground.	0	V
GND_D	Digital ground.	0	V
GND_AB	Anti-blooming ground.	0	V

#### Image Core Biasing Signals

Table 5 summarizes the biasing signals required to drive the IBIS5-A-1300. For optimizations reasons with respect to speed and power dissipation of all internal block several biasing resistors are needed.

Each biasing signal determines the operation of a corresponding module in the sense that it controls the speed and power dissipation. The tolerance on the DC-level of the bias levels can vary ±150 mV due to process variations.

**X-Addressing**

Because of the high pixel rate, the X-shift register selects 2 columns at the time for readout, so it runs at half the system clock speed. All even columns are connected to bus A; all odd columns to bus B. In the output amplifier, bus A and bus B are combined into one stream of pixel data at system clock speed.

At the end of the row blanking time, the X\_SYNC switch is closed while all other switches are open and the decoder output is fed to the register. The decoder loads a logical one in one of the registers and a logical zero in the rest. This defines the starting point of the window in the X direction. As soon as the X\_SYNC signal is released, the register starts shifting from the start position.

When no sub-sampling is required, X\_SUB is inactive. he pointer in the shift-register moves 1 bit at the time.

When sub-sampling is enabled, X\_SUB is activated. The shift register moves 2 bits at the time. Taking into account that every register selects 2 columns, hence 2 pixels sub-sampling results in the pattern “XXOOXXOO” when 8 pixels are considered. Suppose the columns are numbered from left to right starting with 0 (zero) and sub-sampling is enabled:

If columns 1 and 2, 5 and 6, 9 and 10 ... are swapped using the SWAP\_12 switches, a normal sub-sampling pattern of “XOXOXOXO” is obtained.

If columns 3 and 4, 7 and 8, 11 and 12 ... are swapped using the SWAP\_30 switches, the pattern is “OXOXOXOX”.

If both the SWAP\_12 and SWAP\_30 switches are closed, pattern “OOXXOOXX” is obtained.

Because every register addresses 2 columns at the time, the addressable pixels range in sub-sample mode is from 0 to half the maximum number of pixels in a row (only even values). For instance: 0, 2, 4, 6, 8... 638.

**Table 6. X-Sub-sample Patterns**

X_SUB	X_SWAP12	X_SWAP30	Sub-sample Pattern
0	0	0	XXXXXXXX
1	0	0	XXOOXXOO
1	1	0	XOXOXOXO
1	0	1	OXOXOXOX
1	1	1	OOXXOOXX

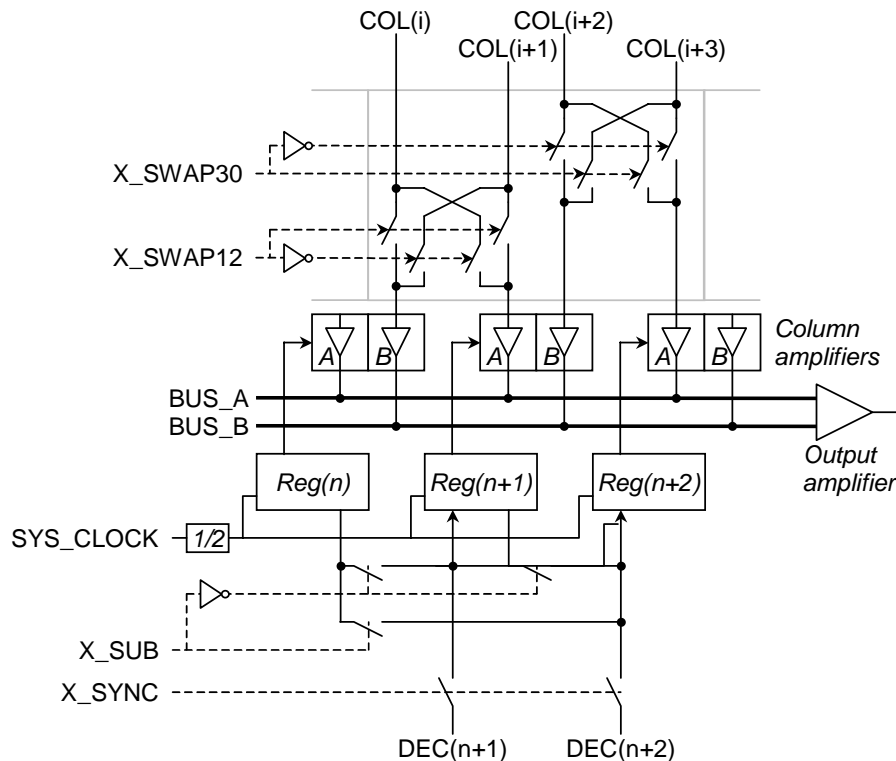

**Y-addressing**

For symmetry reasons, the sub-sampling modes in the Y-direction are the same as in X-direction.

**Table 7. Y-Sub-sample Patterns**

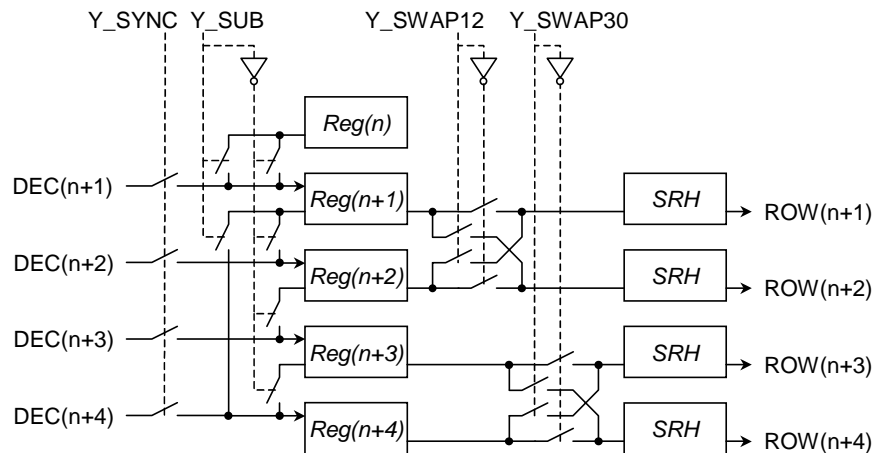

Y_SUB	Y_SWAP12	Y_SWAP30	Sub-sample Pattern
0	0	0	XXXXXXXX
1	0	0	XXOOXXOO
1	1	0	XOXOXOXO

**Figure 6. Column Structure**

**Figure 7. Row Structure**

**Table 7. Y-Sub-sample Patterns**

1	0	1	OXOXOXOX
1	1	1	OXXOXX

In normal mode the pointer for the pixel row is shifted one at the time.

When sub-sampling is enabled, Y\_SYNC is activated. The Y-shift register shifts 2 succeeding bits and skips the 2 next bits. This results in pattern "XXOXXO".

Activating Y\_SWAP12 results in pattern "XOXOXOXO".

Activating Y\_SWAP30 results in pattern "OXOXOXOX".

Activating both Y\_SWAP12 and Y\_SWAP30 results in pattern "OXXOXX".

The addressable pixels range when Y-sub sampling is enabled is: 0-1, 4-5, 8-9, 12-13, ... 1020-1021

### Output Amplifier

#### Architecture and Settings

The output amplifier stage is user-programmable for gain and offset level. Gain is controlled by 4-bit wide word; offset by a 7-bit wide word. Gain settings are on an exponential scale. Offset is controlled by a 7-bit wide DAC, which selects the offset voltage between 2 reference voltages (DAC\_VHIGH and DAC\_VLOW) on a linear scale.

The amplifier is designed to match the specifications of the output of the imager array. This signal has a data rate of 40 MHz and is located between 1.17V and 2.95V. The output impedance of the amplifier is 260Ω.

The output signal has a range between 1.17V and 2.95V, depending on the gain and offset settings of the amplifier. At unity gain and with a mid-range offset value, the amplifier outputs a signal in between 1.59V (light) and 2.70V (dark). This analog range should fit to the input range of the ADC, external or internal. The output swing in unity gain is approximately 1.11V and maximum 1.78V at the highest gain settings.

Figure 8 on page 8 shows the architecture of the output amplifier. The odd and even column amplifiers sample both pixel and reset value to perform a double sampling FPN

-correction. There are 2 different offsets that can be adjusted using the on-chip DAC (7 bit): DAC\_FINE and DAC\_RAW. DAC\_FINE is used to tune the difference between odd and even columns; DAC\_RAW is used to add a general (both even and odd columns) to the FPN corrected pixel value. This pixel value is fed to the first amplifier stage which has an adjustable gain, controlled by a 4-bit word ("GAIN [0...3]").

After this, a unity feedback amplifier buffers the signal and the signal leaves the chip. This 2nd amplifier stage determines the maximal readout speed, that is, the bandwidth and the slew rate of the output signal. The whole amplifier chain is designed for a data rate of 40 Mpix/s (@20 pF).

#### Output Amplifier Gain Control

The output amplifier gain is controlled by a 4-bit word set in the AMPLIFIER register (see section "Amplifier Register (6:0)" on page 15). An overview of the gain settings is given in Table 8.

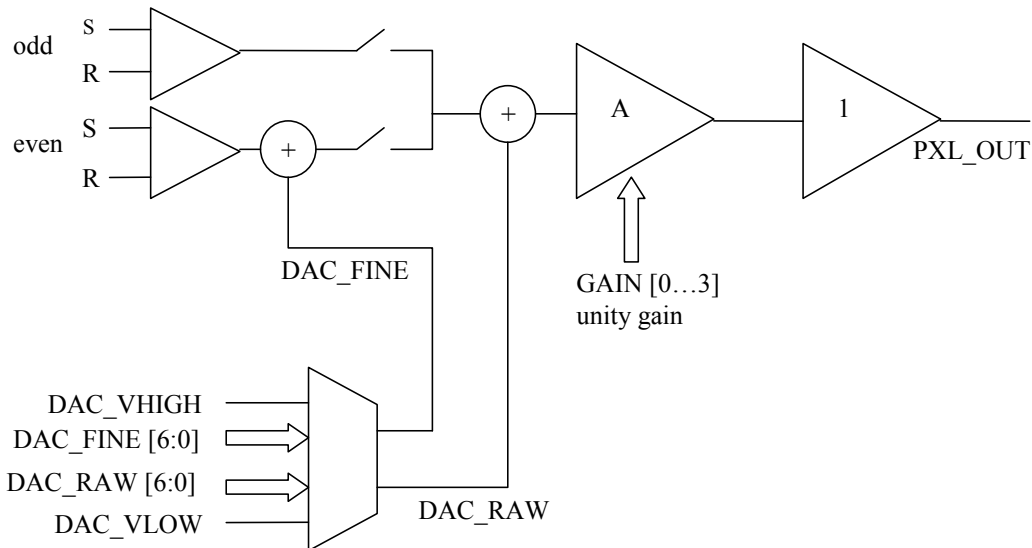

**Table 8. Overview Gain Settings**

bits	DC Gain	bits	DC Gain
0000	1.37	1000	6.25
0001	1.62	1001	7.89
0010	1.96	1010	9.21
0011	2.33	1011	11.00
0100	2.76	1100	11.37
0101	3.50	1101	11.84
0110	4.25	1110	12.32
0111	5.20	1111	12.42

#### Setting of the DAC Reference Voltage

In the output amplifier, the offset can be trimmed by loading registers DACRAW\_REG and DACFINE\_REG. DAC\_RAW is used to adjust the offset of the output amplifier and DAC\_FINE is used to tune the offset between the even and odd columns. These registers are inputs for 2 DACs (see Figure 9 on page 8) that operate on the same resistor that is connected between pins DAC\_VHIGH and DAC\_VLOW. The range of the DAC is defined using a resistive division with R\_VHIGH, R\_DAC and R\_VLOW.

**Figure 8. Output Structure**

**Figure 9. In- and External DAC Connections**

The internal resistor  $R_{DAC}$  has a value of approximately 7.88 k $\Omega$ .

The recommend resistor values for both DAC\_VLOW and DAC\_VHIGH are 0 $\Omega$ .

**Note**

1. The internal ADC range is typically 100 mV lower than the external applied ADC\_VHIGH and ADC\_VLOW voltages due to voltage drops over parasitic internal resistors in the ADC.

**Analog to Digital Converter**

The IBIS5-B-1300 has a 10-bit flash analog digital converter running nominally at 40 Msamples/s. The ADC is electrically separated from the image sensor. The input of the ADC (ADC\_IN; pin 69) should be tied externally to the output (PXL\_OUT1; pin 28) of the output amplifier.

**Table 9. ADC Specifications**

Input range	1–3V <sup>[1]</sup>
Quantization	10 Bits
Nominal data rate	40 Msamples/s
DNL (linear conversion mode)	Typ. < 0.5 LSB
INL (linear conversion mode)	Typ. < 3 LSB
Input capacitance	< 20 pF
Power dissipation @ 40 MHz	Typ. 45 mA * 3.3V = 150 mW
Conversion law	Linear / Gamma-corrected

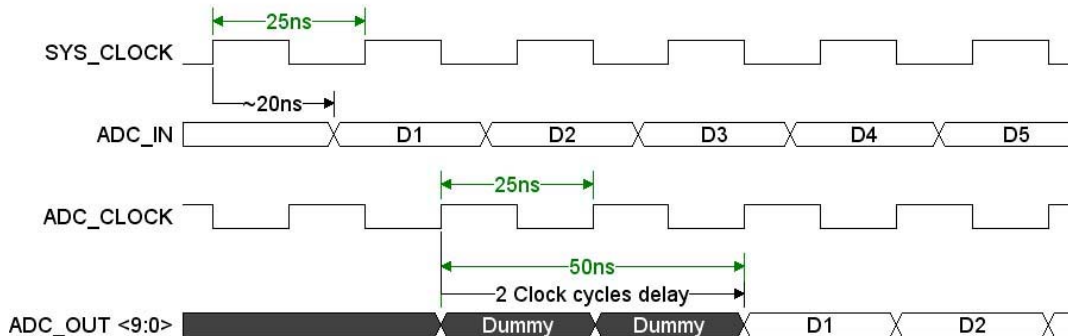

**ADC Timing**

At the rising edge of SYS\_CLOCK the next pixel is fed to the input of the output amplifier. Due to internal delays of the SYS\_CLOCK signal it takes approximately 20 ns before the output amplifier outputs the analog value of the pixel as shown in [Figure 10 on page 9](#).

The ADC converts the pixel data on the rising edge of the ADC\_CLOCK but it takes 2 clock cycles before this pixel data is at the output of the ADC. This pipeline delay is shown in [Figure 10](#).

**Figure 10. ADC Timing**

Due to these delays it is advised that a variable phase difference is foreseen between the ADC\_CLOCK and the SYS\_CLOCK to tune the optimal sample moment of the ADC.

*Setting of the ADC Reference Voltages*

**Figure 11. In- and External ADC Connections**

The internal resistor  $R_{ADC}$  has a value of approximately  $585\Omega$ . This results in the following values for the external resistors:

Resistor	Value (Ω)
$R_{ADC\_VHIGH}$	360
$R_{ADC}$	585
$R_{ADC\_VLOW}$	1200

Note that the recommended ADC resistors value yields in a conversion of the full analog output swing at unity gain ( $V_{DARK\_ANALOG} < ADC\_VHIGH$  and  $V_{LIGHT\_ANALOG} > ADC\_VLOW$ ).

The values of the resistors depend on the value of  $R_{ADC}$ . The voltage difference between  $ADC\_VLOW$  and  $ADC\_VHIGH$  must be at least 1.0V to assure proper working of the ADC.

*Non-linear and Linear Conversion Mode—“gamma” Correction*

Figure 12 on page 10 shows the ADC transfer characteristic. The non-linear (exponential) ADC conversion is intended for gamma-correction of the images. It increases contrast in dark areas and reduces contrast in bright areas. The non-linear transfer function is given by:

$$V_{in} = ADC\_VHIGH + (ADC\_VHIGH - ADC\_VLOW) * \frac{a*x + b*x^2}{a*1023 + b*1023^2}$$

With:

$a = 5$

$b = 0.027$

$x =$  digital output code

**Electronic Shutter Types**

The IBIS5-B-1300 has 2 different shutter types: a rolling (curtain) shutter and a snapshot (synchronous) shutter.

*Rolling (Curtain) Shutter*

The name is due to the fact that the effect is similar to a curtain shutter of a SLR film camera. Although it is a pure electronic operation, the shutter seems to slide over the image. A rolling shutter is easy and elegant to implement in a CMOS sensor. As can be seen in Figure 13 on page 10, there are two Y shift registers. One of them points to the row that is currently being read out. The other shift register points to the row that is currently being reset. Both pointers are shifted by the same Y-clock and move over the focal plane. The integration time is set by the delay between both pointers.

In Figure 13, we schematically indicate the relative shift of the integration times of different lines during the rolling shutter operation. Each line is read and reset in a sequential way. The integration time is the same for all lines, but is shifted in time. The integration time can be varied through the INT\_TIME register (in number of lines).

This indicates to us that all pixels are light sensitive at another period of time, which can cause some blurring if a fast moving object is captured.

When the sensor is set to rolling shutter mode, the input SS\_START and SS\_STOP must best be held low.

**Figure 12. Linear and Non-linear ADC Conversion Characteristic**

**Figure 13. Rolling Shutter Operation**

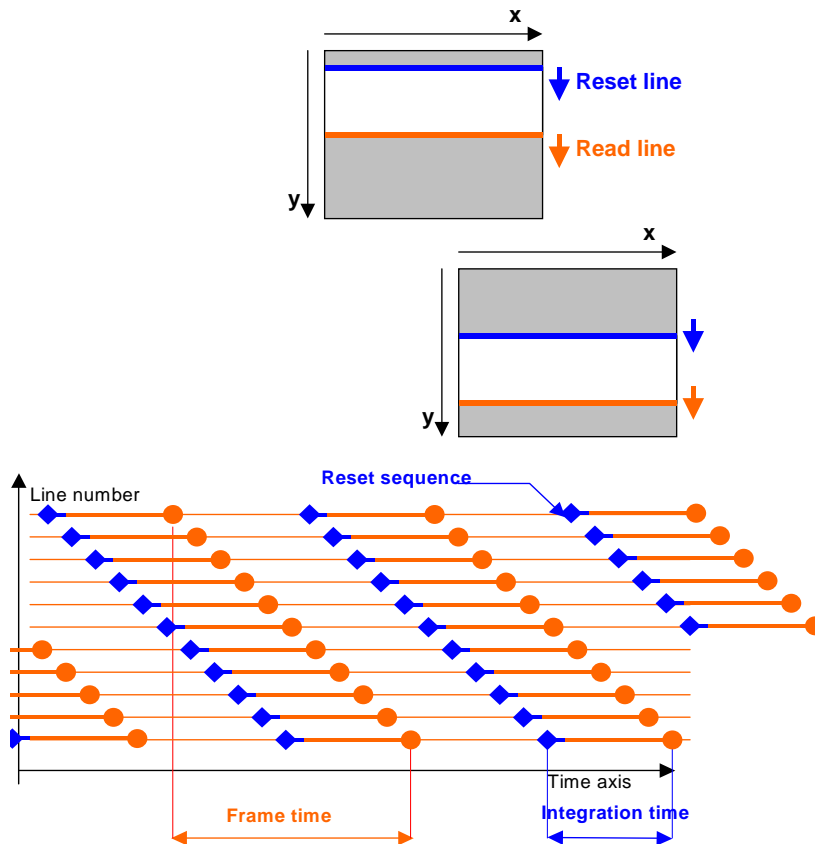

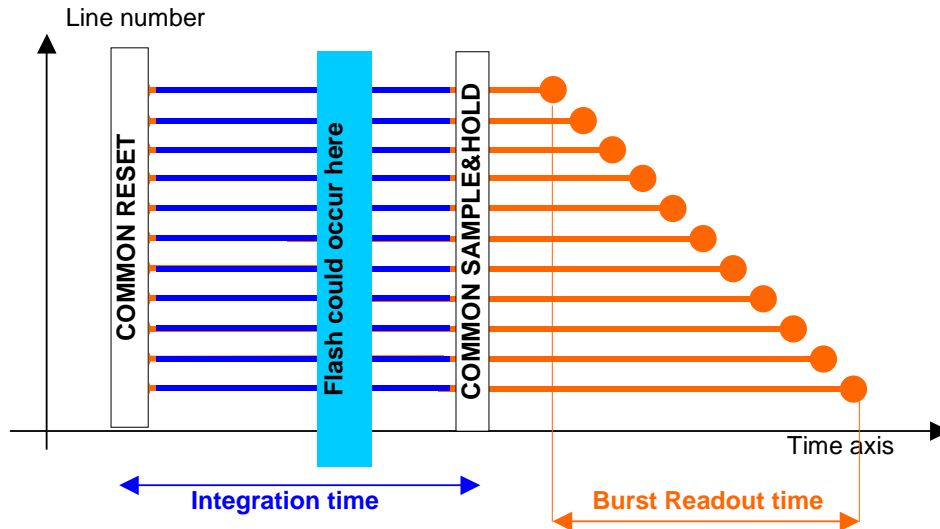

Figure 14. Synchronous Shutter Operation

#### Snapshot (Synchronous) Shutter

A synchronous (global, snapshot) shutter solves the inconvenience found in the rolling shutter. Light integration takes place on all pixels in parallel, although subsequent readout is sequential.

Figure 14 shows the integration and read out sequence for the synchronous shutter. All pixels are light sensitive at the same period of time. The whole pixel core is reset simultaneously and after the integration time all pixel values are sampled together on the storage node inside each pixel. The pixel core is read out line by line after integration. Note that the integration and read out cycle is carry-out in serial, which causes that no integration is possible during read out.

During synchronous shutter the input pins SS\_START and SS\_STOP are used to start and stop the synchronous shutter.

#### Sequencer

Figure 5 on page 4 shows a number of control signals that are needed to operate the sensor in a particular sub-sampling mode with a certain integration time, output amplifier gain, etc.

Most of these signals are generated on-chip by the sequencer that uses only a few control signals. These control signals should be generated by the external system:

- SYS\_CLOCK (X-clock), which defines the pixel rate
- Y\_START pulse, which indicates the start of a new frame read out
- Y\_CLOCK, which selects a new row and starts the row blanking sequence, including the synchronization and loading of the X-register
- SS\_START and SS\_STOP to control the integration period in snapshot shutter mode.

The relative position of the pulses is determined by a number of data bits that are uploaded in internal registers through the serial or parallel interface.

#### Internal Registers

Table 10 on page 12 shows a list of the internal registers with a short description. In the next section, the registers are explained in more detail.

**Table 10. Internal Registers**

Register	Bit	Name	Description
0 (0000)	11:0	SEQUENCER register	Default value <11:0>: "000011000100"
	0	SHUTTER_TYPE	1 = rolling shutter 0 = synchronous shutter
	1	FRAME_CAL_MODE	0 = fast 1 = slow
	2	LINE_CAL_MODE	0 = fast 1 = slow
	3	CONT_CHARGE	1 = "Continuous" precharge enabled.
	4	GRAN_X_SEQ_LSB	Granularity of the X sequencer clock
	5	GRAN_X_SEQ_MSB	
	6	GRAN_SS_SEQ_LSB	Granularity of the SS sequencer clock
	7	GRAN_SS_SEQ_MSB	
	8	KNEEPOINT_LSB	Sets reset voltage for multiple slope operation.
	9	KNEEPOINT_MSB	
	10	KNEEPOINT_ENABLE	1 = Enables multiple slope operation in synchronous shutter mode
11	VDDR_RIGHT_EXT	1 = Disables circuit that generates VDDR_RIGHT voltage so external voltage can be applied.	
1 (0001)	11:0	NROF_PIXELS	Number of pixels to count (maximum 1280/2). Default value <11:0>: "001001111111"
2 (0010)	11:0	NROF_LINES	Number of lines to count. Default value <11:0>: "001111111111"
3 (0011)	11:0	INT_TIME	Integration time. Default value <11:0>: "111111111111"
4 (0100)	10:0	X_REG	X start position (maximum 1280/2). Default value <10:0>: "000000000000"
5 (0101)	10:0	YL_REG	Y-left start position. Default value <10:0>: "000000000000"
6 (0110)	10:0	YR_REG	Y-right start position. Default value <10:0>: "000000000000"
7 (0111)	7:0	IMAGE CORE register	Default value <7:0>: "00000000"
	0	TEST_EVEN	Test even columns.
	1	TEST_ODD	Test odd columns.
	2	X_SUBSAMPLE	Enable sub-sampling in X-direction.
	3	X_SWAP12	Swap columns 1-2, 5-6, ...
	4	X_SWAP30	Swap columns 3-4, 7-8, ...
	5	Y_SUBSAMPLE	Enable sub-sampling in Y-direction.
	6	Y_SWAP12	Swap rows 1-2, 5-6, ...
7	Y_SWAP30	Swap rows 3-4, 7-8, ...	
8 (1000)	6:0	AMPLIFIER register	Default value <6:0>: "1010000"
	0	GAIN<0>	Output amplifier gain setting.
	1	GAIN<1>	
	2	GAIN<2>	
	3	GAIN<3>	
	4	UNITY	1 = Amplifier in unity gain mode.
	5	DUAL_OUT	1 = Activates second output.
	6	STANDBY	0 = Amplifier in standby mode.

**Table 10. Internal Registers** (continued)

Register	Bit	Name	Description
9 (1001)	6:0	DACRAW_REG	Amplifier DAC raw offset. Default value <6:0>: "1000000"
10 (1010)	6:0	DACFINE_REG	Amplifier DAC fine offset. Default value <6:0>: "1000000"
11 (1011)	2:0	ADC register	Default value <2:0>: "011"
	0	TRISTATE_OUT	0 = Output bus in tri-state.
	1	GAMMA	0 = Gamma-correction on.
	2	BIT_INV	1 = Bit inversion on output bus.
12 (1100)		Reserved.	
13 (1101)		Reserved.	
14 (1110)		Reserved.	
15 (1111)		Reserved.	

#### Detailed Description of the Internal Registers

##### Sequencer Register (7:0)

###### 1. Shutter Type (bit 0).

The IBIS5-B-1300 image sensor has 2 shutter types:

0 = synchronous shutter.

1 = rolling shutter.

###### 2. Output Amplifier Calibration (bits 1 and 2).

Bits FRAME\_CAL\_MODE and LINE\_CAL\_MODE define the calibration mode of the output amplifier.

During every row-blanking period, a calibration is done of the output amplifier. There are 2 calibration modes. The FAST mode (= 0) can force a calibration in one cycle but is not so accurate and suffers from KTC noise, while the SLOW mode (= 1) can only make incremental adjustments and is noise free.

Approximately 200 or more "slow" calibrations have the same effect as 1 "fast" calibration.

Different calibration modes can be set at the beginning of the frame (FRAME\_CAL\_MODE bit) and for every subsequent line that is read (LINE\_CAL\_MODE bit). The beginning of a frame is defined by the Y\_START input (see lower), Y\_CLOCK defines the beginning of a new row.

###### 3. Continuous Charge (bit 3).

For some applications it might be necessary to use continuous charging of the pixel columns instead of a pre-charge on every line sample operation.

Setting bit CONT\_CHARGE to "1" activates this function. The resistor connected to pin PC\_CMD is used to control the current level on every pixel column.

###### 4. Internal Clock Granularities (bits 4, 5, 6 and 7).

The system clock is divided several times on-chip.

The X-shift-register that controls the column/pixel readout, is clocked by half the system clock rate. Odd and even pixel

columns are switched to 2 separate buses. In the output amplifier the pixel signals on the 2 buses are combined into one pixel stream at the same frequency as SYS\_CLOCK.

The clock, that drives the "snapshot" or synchronous shutter sequencer, can be programmed using the bits GRAN\_SS\_SEQ\_MSB (bit 7) and GRAN\_SS\_SEQ\_LSB (bit 6).

This way the integration time in synchronous shutter mode can be a multiple of 32, 64, 128 or 256 times the system clock period. To overcome global reset issues it is advised that the longest SS granularity is used (bits 6 and 7 set to '1').

**Table 11. SS Sequencer Clock Granularities**

GRAN_SS_SEQ_MSB/ LSB	SS-sequencer Clock	Integration, Time Step <sup>[2]</sup>
00	32 x SYS_CLOCK	800 ns
01	64 x SYS_CLOCK	1.6 μs
10	128 x SYS_CLOCK	3.2 μs
11	256 x SYS_CLOCK	6.4 μs

The clock that drives the X-sequencer can be a multiple of 4, 8, 16, or 32 times the system clock. Clocking the X-sequencer at a slower rate (longer row blanking time; pixel read out speed is always equal to the SYSTEM\_CLOCK) can result in more signal swing for the same light conditions.

**Table 12. X Sequencer Clock Granularities**

GRAN_X_SEQ_MSB/ LSB	X-sequencer Clock	Row Blanking Time <sup>[2]</sup>
00	4 x SYS_CLOCK	3.5 μs
01	8 x SYS_CLOCK	7 μs
10	16 x SYS_CLOCK	14 μs
11	32 x SYS_CLOCK	28 μs

#### Note

2. Using a SYS\_CLOCK of 40 MHz (25 ns period).

5. Pixel Reset Knee-point for Multiple Slope Operation (bits 8, 9, and 10).

In normal (single slope) mode the pixel reset is controlled from the left side of the image core using the voltage applied on pin VDDR\_LEFT as pixel reset voltage.

In multiple slope operation one or more variable pixel reset voltages have to be applied.

Bits KNEE\_POINT\_MSB and KNEE\_POINT\_LSB select the on chip-generated pixel reset voltage.

Bit KNEE\_POINT\_ENABLE set to "1" switches control to the right side of the image core so the pixel reset voltage (VDDR\_RIGHT), selected by bits KNEE\_POINT\_MSB/LSB, is used.

Bit KNEE\_POINT\_ENABLE should only be used for multiple slope operation in synchronous shutter mode. In rolling shutter mode, only the bits KNEE\_POINT\_MSB/LSB must be used to select the second knee-point in dual slope operation. The actual knee-point depends on VDDH, VDDR\_LEFT and VDDC applied to the sensor.

**Table 13. Multiple Slope Register Settings**

KNEE_POINT		Pixel reset voltage (V)VDDR_RIGHT	Knee-point (V)
MSB/LSB	ENABLE		
00	0 or 1	VDDR_LEFT	0
01	1	VDDR_LEFT - 0.76	+ 0.76
10	1	VDDR_LEFT - 1.52	+ 1.52
11	1	VDDR_LEFT - 2.28	+ 2.28

6. External Pixel Reset Voltage for Multiple Slope (bit 11)

When bit VDDR\_RIGHT\_EXT is set to "1", the circuit that generates the variable pixel reset voltage is disabled and the voltage externally applied to pin VDDR\_RIGHT is used as the double/multiple slope reset voltage.

When bit VDDR\_RIGHT\_EXT is set to "0" the variable pixel reset voltage (used for multiple slope operation) can be monitored on pin VDDR\_RIGHT.

NROF\_PIXELS Register (11:0)

After the internal x\_sync is generated (start of the pixel readout of a particular row), the PIXEL\_VALID signal goes high. The PIXEL\_VALID signal goes low when the pixel counter reaches the value loaded in the NROF\_PIXEL register. Due to the fact that 2 pixels are read at the same clock cycle this number have to be divided by 2 (NROF\_PIXELS = (width of ROI / 2) - 1).

ROF\_LINES Register (11:0)

After the internal yL\_sync is generated (start of the frame readout with Y\_START), the line counter increases with each Y\_CLOCK pulse until it reaches the value loaded in the NROF\_LINES register and an LAST\_LINE pulse is generated.

INT\_TIME Register (11:0)

The INT\_TIME register is used to set the integration time of the electronic shutter. The interpretation of the INT\_TIME depends on the chosen shutter type (rolling or synchronous).

1. Synchronous Shutter.

After the SS\_START pulse is applied an internal counter counts the number of SS granulated clock cycles until it reaches the value loaded in the INT\_TIME register and a TIME\_OUT pulse is generated. This TIME\_OUT pulse can be used to generate the SS\_STOP pulse to stop the integration. When the INT\_TIME register is used the maximum integration time is:

$$TINT\_MAX = 212 * 256 \text{ (maximum granularity)} * (40 \text{ MHz}) - 1 = 26.2 \text{ ms.}$$

This maximum time can be increased if an external counter is used to trigger SS\_STOP. The minimal value that should be loaded into the INT\_TIME register is 10 (see also "Internal Clock Granularities (bits 4, 5, 6 and 7)." on page 13).

2. Rolling Shutter.

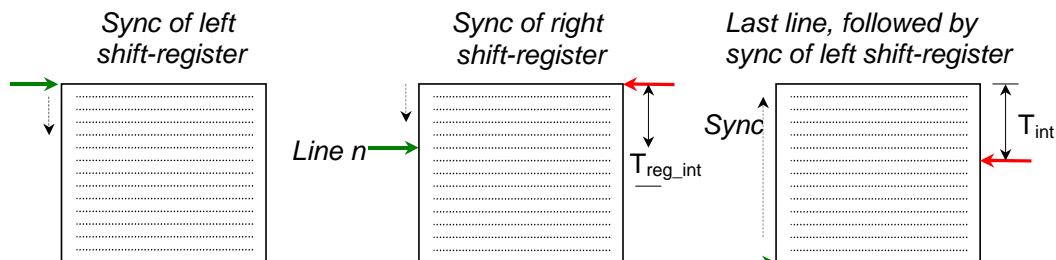

When the Y\_START pulse is applied (start of the frame readout), the sequencer generates the yL\_sync pulse for the left Y-shift register (read out Y-shift register). This loads the left Y-shift register with the pointer loaded in YL\_REG register. At each Y\_CLOCK pulse, the pointer shifts to the next row and the integration time counter increases until it reaches the value loaded in the INT\_TIME register. At that moment, the yR\_sync pulse for the right Y-shift register is generated which loads the right Y-shift register (reset Y-shift register) with the pointer loaded in YR\_REG register (see Figure 15). The integration time counter is reset when the sync for the left Y-shift register is asserted. Both shift registers keep moving until the next sync is asserted (Y\_START for the left Y-shift register and the sync for the right Y-shift register is generated when the integration time counter reaches the INT\_TIME value).

Treg\_int Difference between left and right pointer = value set in the INT\_TIME register (number of lines)

The actual integration time is given by:

$$Tint \text{ Integration time [\# lines]} = \text{NROF\_LINES register} - \text{INT\_TIME register}$$

**Figure 15. Synchronization of the Shift Registers in Rolling Shutter Mode**

#### X\_REG Register (10:0)

The X\_REG register determines the start position of the window in the X-direction. In this direction, there are 640 possible starting positions (2 pixels are addressed at the same time in one clock cycle). If sub sampling is enabled only the even pixels can be set as starting position (for instance: 0, 2, 4, 6, 8... 638).

#### YL\_REG (10:0) and YR\_REG (10:0)

The YL\_REG and YR\_REG registers determine the start position of the window in the Y-direction. In this direction, there are 1024 possible starting positions. In rolling shutter mode the YL\_REG register sets the start position of the read (left) pointer and the YR\_REG sets the start position of the reset (right) pointer. For both shutter types YL\_REG must always be equal to YR\_REG.

#### Image Core Register (7:0)

Bits 1:0 of the IMAGE\_CORE register define the test mode of the image core. Setting 00 is the default and normal operation mode. In case the bit is set to 1, the odd (bit 1) or even (bit 0) columns are tight to the reset level. If the internal ADC is used bits 0 and 1 can be used to create test pattern to test the sample moment of the ADC. If the ADC sample moment is not chosen correctly the created test pattern will not be black-white-black-etc. (IMAGE\_CORE register set at 1 or 2) or black-black-white-white-black-black (IMAGE\_CORE register set at 9) but grey shadings if the sensor is saturated.

Bits 7:2 of the IMAGE\_CORE register define the sub-sampling mode in the X-direction (bits 4:2) and in the Y-direction (bits 7:5). The sub-sampling modes and corresponding bit setting are given in [Table 6 \(Section\)](#) and [Table 7 \(Section\)](#).

#### Amplifier Register (6:0)

##### 1. GAIN (bits 3:0)

The gain bits determine the gain setting of the output amplifier. They are only effective if UNITY = 0. The gains and corresponding bit setting are given in [Table 8 \(Section\)](#).

##### 2. UNITY (bit 4)

In case UNITY = 1, the gain setting of GAIN is bypassed and the gain amplifier is put in unity feedback.

##### 3. DUAL\_OUT (bit 5)

If DUAL\_OUT = 1, the two output amplifiers are active. If DUAL\_OUT = 0, the signals from the two buses are multiplexed to output PXL\_OUT1 which must be connected to ADC\_IN. The gain amplifier and output driver of the second path are put in standby.

#### 4. STANDBY

If STANDBY = 0, the complete output amplifier is put in standby. For normal use, STANDBY must be set to 1.

#### DAC\_RAW Register (6:0) and DAC\_FINE (6:0) Register

These registers determine the black reference level at the output of the output amplifier. Bit setting 111111 for DAC\_RAW register gives the highest offset voltage, bit setting 000000 for DAC\_RAW register gives the lowest offset voltage. Ideally, if the two output paths have no offset mismatch, the DAC\_FINE register must be set to 1000000. Deviation from this value can be used to compensate the internal mismatch (see "Output Amplifier" on page 7).

#### ADC Register (2:0)

##### 1. TRISTATE\_OUT (bit 0)

In case TRISTATE = 0, the ADC\_D<9:0> outputs are in tri-state mode. TRISTATE = 1 for normal operation mode.

##### 2. GAMMA (bit 1)

If GAMMA is set to 1, the ADC input to output conversion is linear; otherwise the conversion follows a 'gamma' law (more contrast in dark parts of the window, lower contrast in the bright parts).

##### 3. BIT\_INV (bit 2)

If BIT\_INV = 1, 0000000000 is the conversion of the lowest possible input voltage, otherwise the bits are inverted.

#### Data Interfaces

Two different data interfaces are implemented. They can be selected using pins IF\_MODE (pin 12) and SER\_MODE (pin 6).

**Table 14. Serial and Parallel Interface Selection**

IF_MODE	SER_MODE	Selected interface
1	X	Parallel
0	1	Serial 3 Wire
0	0	Serial 2 Wire.

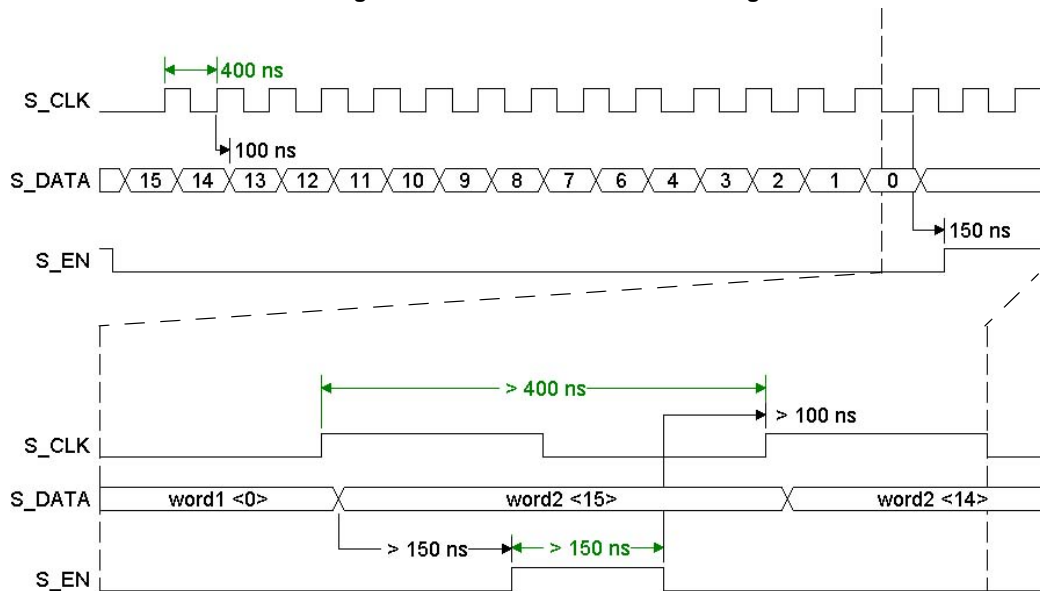

#### Parallel Interface

The parallel interface uses a 16-bit parallel input (P\_DATA <15:0>) to upload new register values. Asserting P\_WRITE loads the parallel data into the internal register of the IBIS5-B-1300 where it is decoded. (See [Figure 16](#). P\_DATA (15:12) Address bits REG\_ADDR (3:0); P\_DATA (11:0) Data bits REG\_DATA (11:0)).

**Figure 16. Parallel Interface Timing**

**Figure 17. Serial-3-wire Interface Timing**

**Serial-3-wire Interface**

The serial-3-wire interface (or Serial-to-Parallel Interface) uses a serial input to shift the data in the register buffer. When the complete data word is shifted into the register buffer the data word is loaded into the internal register where it is decoded. (See Figure 17. S\_DATA (15:12) Address bits REG\_ADDR (3:0); S\_DATA (11:0) Data bits REG\_DATA (11:0). When S\_EN is asserted the parallel data is loaded into the internal registers of the IBIS5-A-1300. The maximum tested frequency of S\_DATA is 2.5 MHz.)

**Serial-2-wire Interface**

The serial-2-wire interface is a unidirectional interface (only register value can be written to the sensor; nothing can be read out). Therefore, the R/W\_N bit (bit 8) is ignored internally. An acknowledge pulse is asserted each time a data word is received successfully. The maximum tested frequency of S\_DATA is 2.5 MHz. (See Figure 18. S\_DATA (15:12) Address bits REG\_ADDR (3:0); S\_DATA (11:0) Data bits REG\_DATA (11:0)).

**Figure 18. Serial-2-wire Interface Timing**

## Timing Diagrams

### Timing Requirements

There are 6 control signals that operate the image sensor:

- SS\_START
- SS\_STOP
- Y\_CLOCK
- Y\_START
- X\_LOAD
- SYS\_CLOCK

These control signals must be generated by the external system with following time constraints to SYS\_CLOCK (rising edge = active edge):

$$T_{SETUP} > 7.5 \text{ ns}$$

$$T_{HOLD} > 7.5 \text{ ns}$$

It is important that these signals are free of any glitches.

Figure 19 shows a recommended schematic for generating the basic signals and to avoid any timing problems.

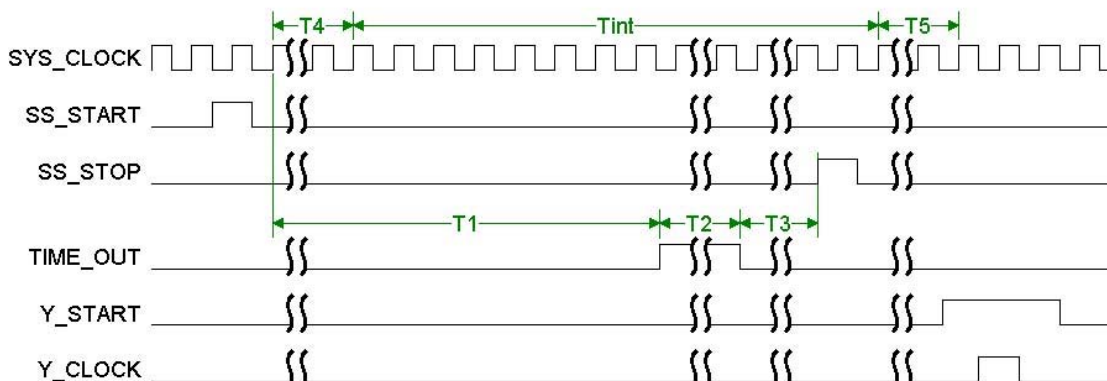

**Figure 19. Recommended Schematic for Generating Basic Signals**

**Figure 20. Relative Timing of the 5 Sequencer Control Signal**

**Figure 21. Synchronous Shutter: Single Slope Integration**

### Synchronous Shutter: Single Slope Integration

SS\_START and SS\_STOP must change on the falling edge of the SYS\_CLOCK ( $T_{setup}$  and  $T_{hold} > 7.5 \text{ ns}$ ). The pulse width of both signals must be a minimum of 1 SYS\_CLOCK cycle. As long as SS\_START or SS\_STOP are asserted, the sequencer stays in a suspended state. (See Figure 21.)

$T_1$ —Time counted by the integration timer until the value of INT\_TIME register is reached. The integration timer is clocked by the granulated SS-sequencer clock.

$T_2$ —TIME\_OUT signal stays high for 1 granulated SS-sequencer clock period.

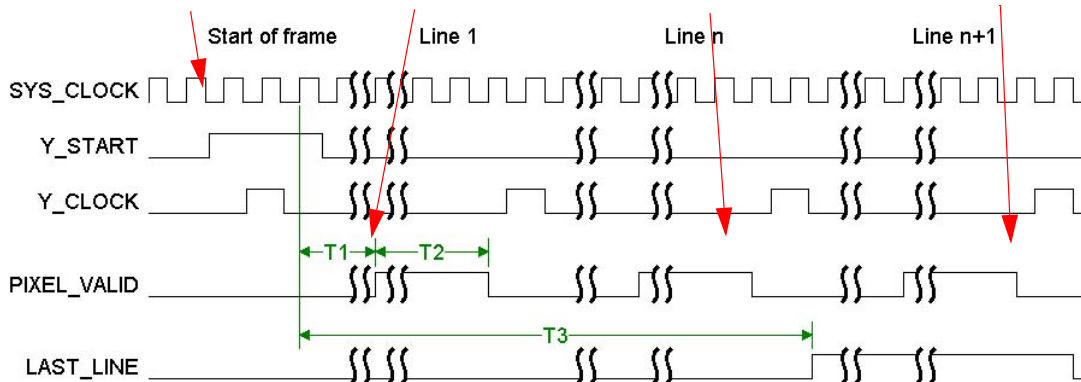

$T_3$ —There are no constraints for this time. The user can use the TIME\_OUT signal to trigger the SS\_STOP pin (or use an external counter to trigger SS\_STOP); both signals cannot be tied together.

$T_4$ —During this time, the SS-sequencer applies the control signals to reset the image core and start integration. This takes 4 granulated SS-sequencer clock periods. The integration time counter starts counting at the first rising edge after the falling edge of SS\_START.

$T_5$ —The SS-sequencer puts the image core in a readable state. It takes 2 granulated SS-sequencer clock periods.

$T_{int}$ —The “real” integration or exposure time.

**Figure 22. Synchronous Shutter: Pixel Read Out**

**Synchronous Shutter: Pixel Readout**

*Basic Operation*

Y\_START and Y\_CLOCK must change on the falling edge of the SYS\_CLOCK ( $T_{setup}$  and  $T_{hold} > 7.5$  ns). The pulse width must be a minimum of 1 clock cycle for Y\_CLOCK and 3 clock cycles for Y\_START. As long as Y\_CLOCK is applied, the sequencer stays in a suspended state. (See Figure 22.)

T<sub>1</sub>—Row blanking time: During this period, the X-sequencer generates the control signals to sample the pixel signal and pixel reset levels (double sampling fpn-correction), and starts the readout of one line. The row blanking time depends on the granularity of the X-sequencer clock (see Table 15).

**Table 15. Row Blanking Time as Function of X-sequencer Granularity**

Granularity N <sub>GRAN</sub>	T <sub>1</sub> (μs) = 35 x N <sub>GRAN</sub> x T <sub>SYS_CLOCK</sub>	GRAN_X_SEQ MSB/LSB
x 4	140 x T <sub>SYS_CLOCK</sub> = 3.5	00
x 8	280 x T <sub>SYS_CLOCK</sub> = 7.0	01
x 16	560 x T <sub>SYS_CLOCK</sub> = 14.0	10
x 32	1120 x T <sub>SYS_CLOCK</sub> = 28.0	11

T<sub>2</sub>—Pixels counted by pixel counter until the value of NROF\_PIXELS register is reached. PIXEL\_VALID goes high when the internal X\_SYNC signal is generated, in other words when the readout of the pixels is started. PIXEL\_VALID goes low when the pixel counter reaches the value loaded in the NROF\_PIXELS register (after a complete row read out).

T<sub>3</sub>—LAST\_LINE goes high when the line counter reaches the value loaded in the NROF\_LINES register and stays high for 1 line period (until the next falling edge of Y-CLOCK).

On Y\_START the left Y-shift-register of the image core is loaded with the YL-pointer that is loaded in to register YL\_REG.

*Pixel Output*

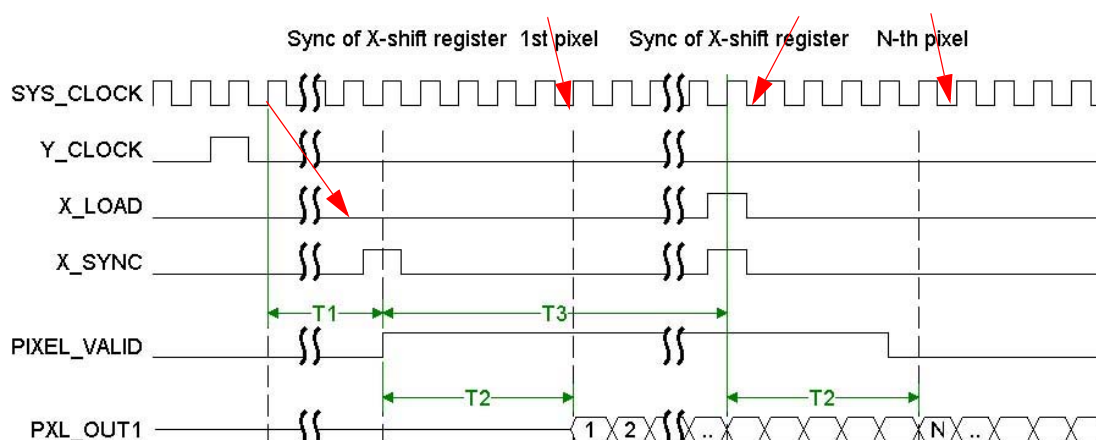

The pixel signal at the PXL\_OUT1 output becomes valid after five SYS\_CLOCK cycles when the internal X\_SYNC (= start of PIXEL\_VALID output or external X\_LOAD pulse) pulse is asserted. (See Figure 23.)

T<sub>1</sub>—Row blanking time (see Table 15).

T<sub>2</sub>—5 SYS\_CLOCK cycles.

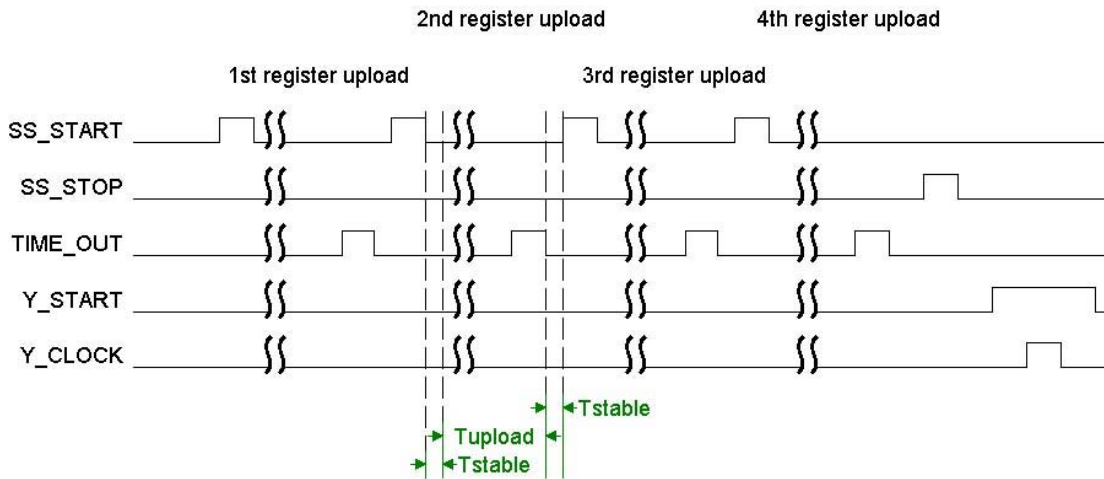

T<sub>3</sub>—Time for new X-pointer position upload in X\_REG register (see "Windowing in X-direction" on page 20 for more details).

**Figure 23. Pixel Output**

**Synchronous Shutter: Multiple Slope Integration**

**Figure 24. Multiple Slope Integration**

Up to four different pixel reset voltages can be used during multiple slope operation in synchronous shutter mode. This is done by uploading new values to register bits KNEEPOINT\_MSB/LSB/ENABLE before a new SS\_START pulse is applied.

Bit KNEEPOINT\_ENABLE must be set high to do a pixel reset with a lower voltage.

Bits KNEEPOINT\_MSB/LSB/ENABLE must be set back to "0" before the SS\_STOP pulse is applied. Every time an SS\_START pulse is applied, the integration time counter is reset.

**Table 16. Multiple Slope Register Settings**

	KNEEPOINT	
	MSB/LSB	ENABLE
Initial set-up	00	0
1st register upload	01	1
2nd register upload	10	1
3th register upload	11	1
4th register upload	00	0

The register upload must be uploaded after time  $T_{stable}$ , otherwise, the change affects the SS-sequencer resulting in a bad pixel reset.  $T_{stable}$  depends on the granularity of the SS-sequencer clock (see Table 17).

**Table 17.  $T_{stable}$  for Different Granularity Settings**

Granularity $N_{GRAN}$	$T_{stable} (\mu s)$ $= 5 \times N_{GRAN} \times T_{SYS\_CLOCK}$	GRAN_SS_SEQ MSB/LSB
x 32	$160 \times T_{SYS\_CLOCK} = 4$	00
x 64	$320 \times T_{SYS\_CLOCK} = 8$	01
x 128	$640 \times T_{SYS\_CLOCK} = 16$	10
x 256	$1280 \times T_{SYS\_CLOCK} = 32$	11

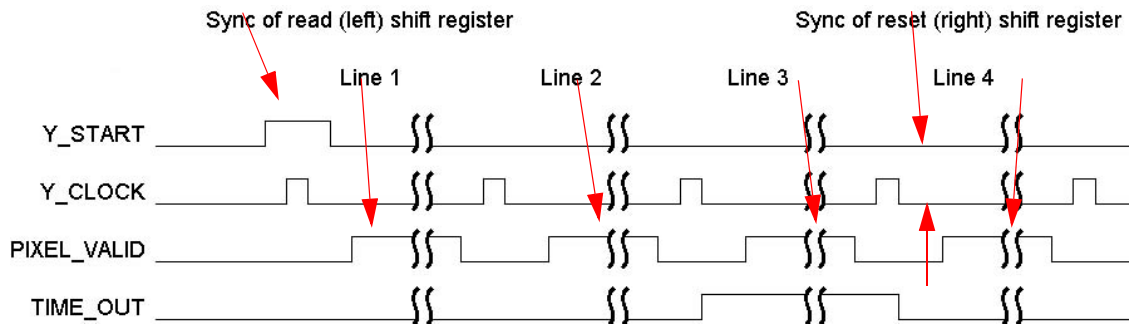

$T_{upload}$  depends on the interface mode used to upload the registers.

**Table 18.  $T_{upload}$  for Different Interface Modes**

Interface mode	$T_{upload} (\mu s)$
Parallel	1
Serial 3-Wire	8

**Rolling Shutter Operation**

**Figure 25. Rolling Shutter Operation**

The integration of the light in the image sensor is done during readout of the other lines.

The only difference with synchronous shutter is that the **TIME\_OUT** pin is used to indicate when the **Y\_SYNC** pulse for the right Y-shift-register (reset Y-shift register) is generated. This loads the right Y-shift-register with the pointer loaded in register **YR\_REG**. The **Y\_SYNC** pulse for the left Y-shift register (read Y-shift register) is generated with **Y\_START**.

The **INT\_TIME** register defines how many lines have to be counted before the **Y\_SYNC** of the right Y-shift-register is generated, hence defining the integration time. See also "INT\_TIME Register (11:0)" on page 14 for a detailed description of the rolling shutter operation.

$T_{int}$  Integration time [# lines] = register(NROF\_LINES) – register(INT\_TIME)

**Note** For normal operation the values of the **YL\_REG** and **YR\_REG** registers are equal.

**Windowing in X-direction**

An **X\_LOAD** pulse overrides the internal **X\_SYNC** signal, loading a new X-pointer (stored in the **X\_REG** register) into the X-shift-register.

The **X\_LOAD** pulse has to appear on the falling edge of **SYS\_CLOCK** and has to remain 2 **SYS\_CLOCK** cycles high overlapping 2 rising edges of **SYS\_CLOCK**. On one of the 2 rising edges of **SYS\_CLOCK** the new X-pointer is loaded.

$T_{load}$  is the available time to upload the register and is defined from the previous register load to the rising edge of **X\_LOAD**. It depends on the settling time of the register and the X-decoder.

The actual time to load the register itself depends on the interface mode that is used.

The parallel interface is the fastest.

**Table 19.  $T_{load}$  for Different Interfaces**

Interface mode	$T_{load}$ ( $\mu$ s)	
Parallel interface	1	(about 40 <b>SYS_CLOCK</b> cycles)
Serial 3 Wire	16	(at 2.5 MHz data rate)

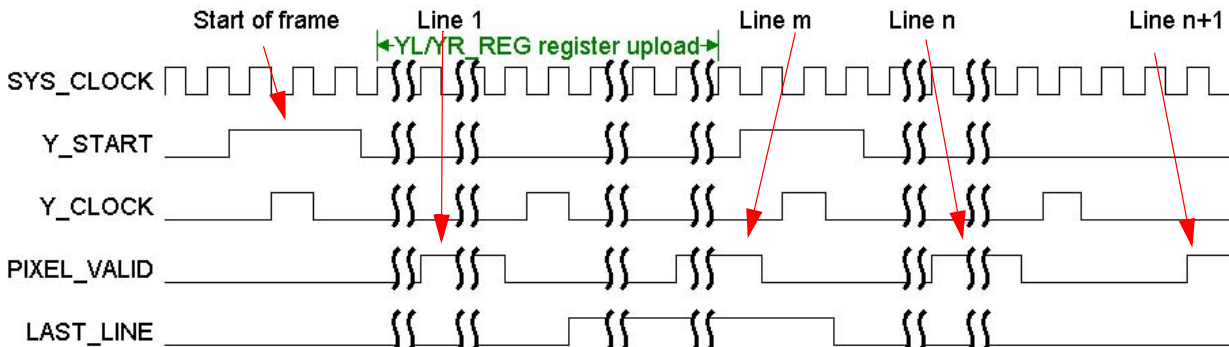

**Figure 26. Windowing in the X-direction**

## Windowing in Y-direction

Figure 27. Windowing in the Y-direction

A new Y-pointer can be loaded into the Y-shift-register, by reapplying the Y\_START pulse after loading a new Y-pointer value into the YL\_REG and YR\_REG registers.

Every time a Y\_START pulse appears, a frame calibration of the output amplifier is performed.

### Initialization (start-up behavior)

To avoid any high current consumption at start-up, it is recommended to apply the SYS\_CLOCK signal as soon as possible after or even before power-on of the image sensor.

After power-on of the image sensor, it is recommended to apply SYS\_RESET for a minimum of 5 SYS\_CLOCK periods to ensure a proper reset of the on-chip sequencer and timing circuitry. All internal registers will be set to '0' after SYS\_RESET is applied.

Since all the IBIS5-B-1300 control signals are active high, it is also recommended to apply a low level (before SYS\_RESET occurs) to these pins at start up to avoid latch up.

## Pin List

The IBIS5-B-1300 image sensor is packaged in a leadless ceramic carrier (LCC package). Table 20 is a list of all the pins and their functions. In total, there are 84 pins.

**Table 20.** Pin List<sup>[3, 4, 5]</sup>

Pin	Pin Name	Pin Type	Pin Description
1	P_DATA<8>	Input	Digital input. Data parallel interface.
2	P_WR	Input	Digital input (active high). Parallel write.
3	S_CLK	Input	Digital input. Clock signal of serial interface.
4	S_DATA	Input	Digital input/output. Data of serial interface.
5	S_EN	Input	Digital input (active low). Enable of Serial-3-wire interface.
6	SER_MODE	Input	Digital input. Serial mode enable (1 = Enable serial-3-wire, 0 = Enable serial-2-wire).
7	VDDC	Supply	Analog supply voltage. Supply voltage of the pixel core [3.3V].
8	VDDA	Supply	Analog supply voltage. Analog supply voltage of the image sensor [3.3V].
9	GNDA	Ground	Analog ground. Analog ground of the image sensor.
10	GNDD	Ground	Digital ground. Digital ground of the image sensor.
11	VDDD	Supply	Digital supply voltage. Digital supply voltage of the image sensor [3.3V].
12	IF_MODE	Input	Digital input. Interface mode (1 = parallel; 0 = serial).
13	DEC_CMD	Input	Analog input. Biasing of decoder stage. Connect to VDDA with R = 50 kΩ and decouple with C = 100 nF to GNDA.
14	Y_START	Input	Digital input (active high). Start frame read out.
15	Y_CLOCK	Input	Digital input (active high). Line clock.
16	LAST_LINE	Output	Digital output. Generates a high level when the last line is read out.
17	X_LOAD	Input	Digital input (active high). Loads new X-position during read out.
18	SYS_CLOCK	Input	Digital input. System (pixel) clock (40 MHz).
19	PXL_VALID	Output	Digital output. Generates high level during pixel read out.
20	SS_START	Input	Digital input (active high). Start synchronous shutter operation.
21	SS_STOP	Input	Digital input (active high). Stop synchronous shutter operation.
22	TIME_OUT	Output	Digital output. Synchronous shutter: pulse when time-out reached. Can be used to trigger SS_STOP although both signals can't be tied together. Rolling shutter: pulse when second Y-sync appears.
23	SYS_RESET	Input	Digital input (active high). Global system reset.
24	EL_BLACK	Input	Digital input (active high). Enables electrical black in output amplifier.
25	EOSX	Output	Digital output. Diagnostic end-of-scan of X-register.
26	DAC_VHIGH	Input	Analog reference input. Biasing of DAC for output dark level. Can be used to set output range of DAC. Default: Connect to VDDA with R = 0Ω.
27	DAC_VLOW	Input	Analog reference input. Biasing of DAC for output dark level. Can be used to set output range of DAC. Default: Connect to GND A with R = 0Ω.
28	PXL_OUT1	Output	Analog output. Analog pixel output 1.
29	PXL_OUT2	Output	Analog output. Analog pixel output 2. Leave not connected if not used.
30	AMP_CMD	Input	Analog input. Biasing of the output amplifier. Connect to VDDA with R = 50 kΩ and decouple with C = 100 nF to GNDA.

### Notes

3. All pins with the same name can be connected together.
4. All digital input are active high (unless mentioned otherwise).
5. Digital inputs that are not used must be tied to GND (inactive level).

**Table 20. Pin List**<sup>[3, 4, 5]</sup> (continued)

Pin	Pin Name	Pin Type	Pin Description
31	COL_CMD	Input	Analog input. Biasing of the column amplifiers. Connect to VDDA with R = 50 k $\Omega$ and decouple with C = 100 nF to GNDA.
32	PC_CMD	Input	Analog input. Pre-charge bias. Connect to VDDA with R = 25 k $\Omega$ and decouple with C = 100 nF to GNDA.
33	VDDD	Supply	Digital supply. Digital supply voltage of the image sensor [3.3V].
34	GNDD	Ground	Digital ground. Digital ground of the image sensor.
35	GNDA	Ground	Analog ground. Analog ground of the image sensor.
36	VDDA	Supply	Analog supply voltage. Analog supply voltage of the image sensor [3.3V].
37	VDDC	Supply	Analog supply voltage. Supply voltage of the pixel core [3.3V].
38	P_DATA<0>	Input	Digital input. Data parallel interface (LSB).
39	P_DATA<1>	Input	Digital input. Data parallel interface.
40	P_DATA<2>	Input	Digital input. Data parallel interface.
41	P_DATA<3>	Input	Digital input. Data parallel interface.
42	P_DATA<4>	Input	Digital input. Data parallel interface.
43	P_DATA<5>	Input	Digital input. Data parallel interface.
44	P_DATA<6>	Input	Digital input. Data parallel interface.
45	P_DATA<7>	Input	Digital input. Data parallel interface.
46	SI2_ADDR<0>	Input	Digital input. Sets I2C address.
47	SI2_ADDR<1>	Input	Digital input. Sets I2C address.
48	SI2_ADDR<2>	Input	Digital input. Sets I2C address.
49	SI2_ADDR<3>	Input	Digital input. Sets I2C address.
50	SI2_ADDR<4>	Input	Digital input. Sets I2C address.
51	GNDAB	Supply	Analog supply voltage. Anti-blooming ground.
52	VDDR_RIGHT	Supply	Analog supply voltage. Variable reset voltage (multiple slope operation). Decouple with 1 $\mu$ F to GNDA.
53	ADC_VLOW	Input	Analog reference input. ADC low reference voltage. Default: Connect to GNDA with R = 1200 $\Omega$ and decouple with C = 100 nF to GNDA.
54	ADC_GNDA	Ground	Analog ground. ADC analog ground.
55	ADC_VDDA	Supply	Analog supply voltage. ADC analog supply voltage [3.3V].
56	ADC_GNDD	Ground	Digital ground. ADC digital ground.
57	ADC_VDDD	Supply	Digital supply voltage. ADC digital supply voltage [3.3V].
58	ADC_CLOCK	Input	Digital input. ADC clock (40 MHz).
59	ADC_OUT<9>	Output	Digital output. ADC data output (MSB).
60	ADC_OUT<8>	Output	Digital output. ADC data output.
61	ADC_OUT<7>	Output	Digital output. ADC data output.
62	ADC_OUT<6>	Output	Digital output. ADC data output.
63	ADC_OUT<5>	Output	Digital output. ADC data output.
64	ADC_OUT<4>	Output	Digital output. ADC data output.
65	ADC_OUT<3>	Output	Digital output. ADC data output.
66	ADC_OUT<2>	Output	Digital output. ADC data output.
67	ADC_OUT<1>	Output	Digital output. ADC data output.
68	ADC_OUT<0>	Output	Digital output. ADC data output (LSB).
69	ADC_IN	Input	Analog input. ADC analog input.
70	ADC_CMD	Input	Analog input. Biasing of the input stage of the ADC. Connect to ADC_VDDA with R = 50 k $\Omega$ and decouple with C = 100 nF to ADC_GNDA.

**Table 20. Pin List**<sup>[3, 4, 5]</sup> (continued)

Pin	Pin Name	Pin Type	Pin Description
71	ADC_VDDD	Supply	Digital supply voltage. ADC digital supply voltage [3.3V].
72	ADC_GNDA	Ground	Analog ground. ADC analog ground.
73	ADC_GNDD	Ground	Digital ground. ADC digital ground.
74	ADC_VDDA	Supply	Analog supply voltage. ADC analog supply voltage [3.3V].
75	ADC_VHIGH	Input	Analog reference input. ADC high reference voltage. Default: Connect to VDDA with R = 360Ω and decouple with C = 100 nF to GNDA.
76	VDDR_LEFT	Supply	Analog supply voltage. High reset level [4.5V].
77	VDDH	Supply	Analog supply voltage. High supply voltage for HOLD switches in the image core [4.5V]
78	P_DATA<15>	Input	Digital input. Data parallel interface (MSB).
79	P_DATA<14>	Input	Digital input. Data parallel interface.
80	P_DATA<13>	Input	Digital input. Data parallel interface.
81	P_DATA<12>	Input	Digital input. Data parallel interface.
82	P_DATA<11>	Input	Digital input. Data parallel interface.
83	P_DATA<10>	Input	Digital input. Data parallel interface.
84	P_DATA<9>	Input	Digital input. Data parallel interface.

**Specifications**

**General Specifications.**

**Table 21. General Specifications**

Parameter	Specification	Remarks
Pixel architecture	4T-pixel	High fill factor square pixels (based on the high-fill factor active pixel sensor technology of Cypress). Patents pending.
Pixel size	6.7 μm x 6.7 μm	The resolution and pixel size results in a 2/3" optical format.
Resolution	1280 x 1024	
Pixel rate	40 MHz	Using a 40 MHz system clock.
Shutter type	<ul style="list-style-type: none"> <li>• Electronic rolling shutter</li> <li>• Snapshot shutter</li> </ul>	<ul style="list-style-type: none"> <li>• Continuous imaging.</li> <li>• Triggered global shutter with integration and readout separate in time.</li> </ul>
Full frame rate	27 frames/second	Increases with ROI read out and/or sub sampling.

**Electro-optical Specifications**

*Overview*

**Table 22. Electro-Optical Specifications**

Parameter	Specification	Remarks
FPN (local)	<0.20%	RMS % of saturation signal.
PRNU (local)	<10%	Peak-to-peak of signal level.
Conversion gain	17.6 μV/electron	@ output (measured).
Output signal amplitude	1V	At nominal conditions.
Saturation charge	62.500 e-	
Sensitivity (peak)	715V.m2/W.s 8.40 V/lux.s	@ 650 nm (85 lux = 1 W/m2).
Sensitivity (visible)	572 V.m2/W.s 3.51 V/lux.s	400-700 nm (163 lux = 1 W/m2).
Peak QE * FF Peak Spectral Resp.	30%0.16 A/W	Average QE*FF = 22% (visible range). Average SR*FF = 0.1 A/W (visible range). See spectral response curve.
Fill factor	40%	Light sensitive part of pixel (measured).
Dark current	7.22 mV/s 410e-/s	Typical value of average dark current of the whole pixel array (@ 21 °C).
Dark Signal Non Uniformity	7 mV/s 400 e-/s	Dark current RMS value (@ 21 °C).
Temporal noise	40 RMS e-	Measured at digital output (in the dark).
S/N Ratio	1563:1 (64 dB)	Measured at digital output (in the dark).
Spectral sensitivity range	400 - 1000 nm	
Optical cross talk	16%	To the first neighboring pixel.
Parasitic Sensitivity	3%	Averaged over spectrum
Power dissipation	175 mWatt	Typical (including ADCs).

Spectral Response Curve

Figure 28. Spectral response curve

Figure 28 shows the spectral response characteristic for the IBIS5-B-1300 (CYII5SM1300AB) and the IBIS-5-BE-1300 (CYII5FM1300AB). The curve is measured directly on the pixels. It includes effects of non-sensitive areas in the pixel, e.g., interconnection lines. The sensor is light-sensitive between 400 and 1000 nm. The peak QE \* FF is 30% approx-

imately around 650 nm. In view of a fill factor of 40%, the QE is thus close to 75% between 500 and 700 nm. The IBIS5-BE-1300 has superior response in the NIR region (700-900 nm). For more information about the IBIS5-B-1300, refer to "IBIS5-BE-1300 (CYII5FM1300AB)" on page 27.

Electro-voltaic Response Curve

**Figure 29. Electro-voltaic Response Curve**

Figure 29 shows the pixel response curve in linear response mode. This curve is the relation between the electrons detected in the pixel and the output signal. The resulting voltage-electron curve is independent of any parameters (integration time, etc.). The voltage to electrons conversion gain is 17.6  $\mu\text{V}/\text{electron}$ .

*IBIS5-BE-1300 (CYII5FM1300AB)*

The IBIS5-BE-1300 is processed on a thicker epitaxial Si layer featuring a superb sensitivity in the NIR (Near Infra Red) wavelengths (700-900 nm). The spectral response curves of the two IBIS5-B-1300 image sensors are shown in Figure 28 on page 26. As many machine vision applications use light sources in the NIR, the IBIS5-BE-1300 sensor has a significant sensitivity advantage in the NIR.

A drawback of the thicker epitaxial layer is a slight performance decrease in MTF (Modular Transfer Function or electrical pixel to pixel cross-talk) as indicated in the table below.

**Table 23.MTF comparison**

Direction	Wavelength	IBIS5-B-1300	IBIS5-BE-1300
Horizontal	600	0.58	0.37
Horizontal	700		0.18
Horizontal	800		0.16
Horizontal	900		0.07
Vertical	600	0.53	0.26
Vertical	700		0.16
Vertical	800		0.13
Vertical	900		0.11

The resulting image sharpness is hardly affected by this decreased MTF value.

Both IBIS5-B-1300 versions are fully pin compatible and have identical timing and biasing

**Features and General Specifications**
**Table 24. Features and General Specifications**

Feature	Specification/Description
Electronic shutter types	1. Rolling curtain shutter. 2. Synchronous (snapshot) shutter.
Windowing (ROI)	Implemented as scanning of lines/columns from an uploaded position.
Sub-sampling modes:	1:2 sub-sampling. Sub-sampling patterns: XXOOXXOO (for Bayer pattern color filter) OOXXOOXX (for Bayer pattern color filter) XOXOXOXOXOXOXOX Identical sub-sample patterns in X- and Y-direction.
Extended dynamic range	In rolling shutter: Normal (1) or double (2) slope. In Synchronous shutter: 1, 2, 3 or 4 slopes.
Digital output	10 bit ADC @ 40 MSamples/s.
Programmable gain range	x1 to x12, in 16 steps of approx. 1.5 dB using 4-bit programming.
Programmable offset	128 steps (7 bit).
Supply voltage VDD	Image core supply: Range from 3.0V to 4.5V Analog supply: Nominal 3.3V Digital: Nominal 3.3V
Logic levels	3.3 V (Digital supply).
Operational temperature range	-30°C to 65°C, with degradation of dark current.
Die size (with scribe lines)	10.1 mm by 9.3 mm (x by y).
Package	84 pins LCC.

**Electrical Specifications**
*Absolute Maximum Ratings*
**Table 25. Absolute Maximum Ratings**

Parameter	Description	Value	Unit
VDD	DC supply voltage	-0.5 to 4.5	V
V <sub>IN</sub>	DC input voltage	-0.5 to 3.8	V
V <sub>OUT</sub>	DC output voltage	-0.5 to 3.8	V
I <sub>IO</sub>	DC current drain per pin; any single input or output.	± 50	mA
T <sub>L</sub>	Lead temperature (5 seconds soldering).	350	°C
T <sub>ST</sub>	Storage temperature	-30 to +85	°C
H	Humidity (relative)	85% at 85°C	
ESD	ESD susceptibility	2000	V

VDD = VDDD = VDDA (VDDD is supply to digital circuit, VDDA to analog circuit).

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections are not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*Recommended Operating Conditions*
**Table 26. Recommended Operating Conditions**

Parameter	Description	Min.	Typ.	Max.	Unit
VDDH	Voltage on HOLD switches.	+3.3	+4.5	+4.5	V
VDDR_LEFT	Highest reset voltage.	+3.3	+4.5	+4.5	V
VDDC	Pixel core voltage.	+2.5	+3.0	+3.3	V
VDDA	Analog supply voltage of the image core.	+3.0	+3.3	+3.6	V
VDDD	Digital supply voltage of the image core.	+3.0	+3.3	+3.6	V
GND A	Analog ground	-0.5	0	+0.5	V
GND D	Digital ground	-0.5	0	+0.5	V
GND_AB	Anti-blooming ground.	-0.5	0	+0.5	V
T <sub>A</sub>	Commercial operating temperature.	0	30	60	°C

All parameters are characterized for DC conditions after thermal equilibrium has been established.

Unused inputs must always be tied to an appropriate logic level, e.g., either VDD or GND.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is recommended that normal precautions be taken to avoid application of any voltages higher than the maximum rated voltages to this high impedance circuit.

*DC Electrical Characteristics*
**Table 27. DC Electrical Characteristics**

Parameter	Characteristic	Condition	Min.	Max.	Unit
V <sub>IH</sub>	Input high voltage		2.1		V
V <sub>IL</sub>	Input low voltage			0.6	V
I <sub>IN</sub>	Input leakage current	V <sub>IN</sub> = VDD or GND	-10	+10	μA
V <sub>OH</sub>	Output high voltage	VDD = min; I <sub>OH</sub> = -100 mA	2.2		V
V <sub>OL</sub>	Output low voltage	VDD = min; I <sub>OH</sub> = 100 mA		0.5	V
I <sub>DD</sub>	Maximum operating current	System clock ≤ 40 MHz	40	60	mA

## Pad position and Packaging

### Bare Die

The IBIS5-B-1300 image sensor has 84 pins, 21 pins on every edge. The die size from pad-edge to pad-edge (without scribe-line) is: 10156.5  $\mu\text{m}$  (x) by 9297.25  $\mu\text{m}$  (y). Scribe lines take about 100 to 150  $\mu\text{m}$  extra on each side. Pin 1 is located in the middle of the left side, indicated by a "1" on the layout. A logo and some identification tags can be found on the top right of the die.

**Figure 30. IBIS5-B-1300 Bare Die Dimensions (All dimensions in  $\mu\text{m}$ )**

**IBIS5-B-1300 in 84-pin LCC Package**

### Cover Glass

A D263 glass lid (which has a refraction index of 1.52) is used as a protection glass lid on top of all IBIS5-B-1300 sensors. [Figure 41](#) shows the transmission characteristics of the D263 glass.

Figure 41. Transmission Characteristics of the D263 Glass

**Storage and Handling**

**Storage Conditions**

**Table 29.Storage Conditions**

Description	Minimum	Maximum	Units
Temperature	-30	+85	°C

**Handling and Soldering Conditions**

Special care must be taken when soldering image sensors with color filter arrays (RGB color filters) onto a circuit board since color filters are sensitive to high temperatures. Prolonged heating at elevated temperatures may result in deterioration of the performance of the sensor. The following recommendations are made to ensure that sensor performance is not compromised during end-users' assembly processes.

*Board Assembly*

Device placement onto boards must be done in accordance with strict ESD controls for Class 0, JESD22 Human Body Model, and Class A, JESD22 Machine Model devices. Assembly operators must always wear all designated and approved grounding equipment; grounded wrist straps at ESD protected workstations are recommended including the use of ionized blowers. All tools must be ESD protected.

*Manual Soldering*

When a soldering iron is used the following conditions must be observed:

Use a soldering iron with temperature control at the tip. The soldering iron tip temperature must not exceed 350°C.

The soldering period for each pin must be less than 5 seconds.

*Reflow Soldering*

Figure 42 shows the maximum recommended thermal profile for a reflow soldering system. If the temperature/time profile

exceeds these recommendations damage to the image sensor may occur. See Figure 42 for more details.

*Precautions and Cleaning*

Avoid spilling solder flux on the cover glass; bare glass and particularly glass with antireflection filters may be adversely affected by the flux. Avoid mechanical or particulate damage to the cover glass.

It is recommended that isopropyl alcohol (IPA) be used as a solvent for cleaning the image sensor glass lid. When using other solvents, it must be confirmed beforehand whether or not the solvent will dissolve the package and/or the glass lid.

**RoHS (lead-free) Compliance**

This paragraph reports the use of Hazardous chemical substances as required by the RoHS Directive (excluding packing material).

**Table 30.The Chemical Substances and Information about Any Intentional Content**

Chemical Substance	Any intentional content?	If there is any intentional content, in which portion is it contained?
Lead	NO	-
Cadmium	NO	-
Mercury	NO	-
Hexavalent chromium	NO	-
PBB (Polybrominated biphenyls)	NO	-
PBDE (Polybrominated diphenyl ethers)	NO	-

**Figure 42. Reflow Soldering Temperature Profile**

*Information on Lead-free Soldering:*

IBIS5-B-1300-M2 (serial numbers beyond 3694): the product was tested successfully for lead-free soldering processes, using a reflow temperature profile with maximum 260°C, minimum 40s at 255°C and minimum 90s at 217°C.

**Note**

“Intentional content” is defined as any material demanding special attention is contained into the inquired product by following cases:

1. A case that the above material is added as a chemical composition into the inquired product intentionally in order to

produce and maintain the required performance and function of the intended product

2. A case that the above material, which is used intentionally in the manufacturing process, is contained in or adhered to the inquired product

The following case is not treated as “intentional content”:

1. A case that the above material is contained as an impurity into raw materials or parts of the intended product. The impurity is defined as a substance that cannot be removed industrially, or it is produced at a process such as chemical composing or reaction and it cannot be removed technically.

**Ordering Information**

**Notes**

6. JLCC package for use in evaluation kits only.
  7. D263 is used as protective cover glass lid (see [Figure 41](#) for spectral transmittance).
  8. The CYII5FM1300AB has a thicker epitaxial Si layer for enhanced sensitivity in the NIR region
  9. The 126 BGA case package is currently only offered on a sample base.
- Other packaging combinations are available upon special request.  
Contact your local Cypress sales office for more information about part names, prices and availability.

### Appendix A: IBIS5 Evaluation System

For evaluating purposes an IBIS5 evaluation kit is available. The IBIS5 evaluation kit consists of a multifunctional digital board (memory, sequencer and IEEE 1394 Fire Wire interface) and an analog image sensor board.

Visual Basic software (under Win 2000™ or XP™) allows the grabbing and display of images and movies from the sensor. All acquired images and movies can be stored in different file formats (8 or 16-bit). All setting can be adjusted on the fly to evaluate the sensors specs. Default register values can be loaded to start the software in a desired state.

**Figure 43. Content of the IBIS5 Evaluation Kit**
