### Description

The CY29949 is a low voltage 200 MHz clock distribution buffer with the capability to select either a differential LVPECL or LVCMOS/LVTTL compatible input clocks. These clock sources are used to provide for test clocks and primary system clocks. All other control inputs are LVCMOS/LVTTL compatible. The 15 outputs are LVCMOS or LVTTL compatible and can drive 50Ω series or parallel terminated transmission lines. For series terminated transmission lines, each output can drive one or two traces giving the device an effective fanout of 1:30.

The CY29949 is capable of generating 1X and 1/2X signals from a 1X source. These signals are generated and retimed internally to ensure minimal skew between the 1X and 1/2X signals. SEL(A:D) inputs allow flexibility in selecting the ratio of 1X to 1/2X outputs.

The CY29949 outputs can also be three-stated via the MR/OE# input. When MR/OE# is set HIGH, it resets the internal flip-flops and three-states the outputs.

Maximum Input Voltage Relative to  $V_{SS}$ :.....  $V_{SS} - 0.3V$   
 Maximum Input Voltage Relative to  $V_{DD}$ :.....  $V_{DD} + 0.3V$   
 Storage Temperature:.....  $-65^{\circ}C$  to  $+150^{\circ}C$   
 Operating Temperature:.....  $-40^{\circ}C$  to  $+85^{\circ}C$

 Maximum Input Current: .....  $\pm 20$  mA

This device contains circuitry to protect the inputs against damage due to high static voltages or electric field; however, precautions must be taken to avoid application of any voltage higher than the maximum rated voltages to this circuit. For proper operation,  $V_{in}$  and  $V_{out}$  should be constrained to the range:

$$V_{SS} < (V_{in} \text{ or } V_{out}) < V_{DD}$$

Unused inputs must always be tied to an appropriate logic voltage level (either  $V_{SS}$  or  $V_{DD}$ ).

**Notes**

- Multiple Supplies: The voltage on any input or I/O pin cannot exceed the power pin during power up. Power supply sequencing is NOT required.
- Inputs have pull-up/pull-down resistors that effect input current.
- The  $V_{CMR}$  is the difference from the most positive side of the differential input signal. Normal operation is obtained when the "High" input is within the  $V_{CMR}$  range and the input lies within the  $V_{PP}$  specification.
- Driving series or parallel terminated  $50\Omega$  (or  $50\Omega$  to  $V_{DD}/2$ ) transmission lines.
