

## 2.5 V and 3.3 V LVCMOS Clock Fanout Buffer

The MPC9443 is a 2.5 V and 3.3 V compatible 1:16 clock distribution buffer designed for low-voltage high-performance telecom, networking and computing applications. The device supports 3.3 V, 2.5 V and dual supply voltage (mixed-voltage) applications. The MPC9443 offers 16 low-skew outputs which are divided into 4 individually configurable banks. Each output bank can be individually supplied by 2.5 V or 3.3 V, individually set to run at 1X or 1/2X of the input clock frequency or be disabled (logic low output state). Two selectable LVPECL compatible inputs support differential clock distribution systems. In addition, one selectable LVCMOS input is provided for LVCMOS clock distribution systems. The MPC9443 is specified for the extended temperature range of  $-40$  to  $+85^{\circ}\text{C}$ .

### Features

- Configurable 16 outputs LVCMOS clock distribution buffer
- Compatible to single, dual and mixed 3.3 V / 2.5 V voltage supply
- Output clock frequency up to 350 MHz
- Designed for high-performance telecom, networking and computer applications
- Supports applications requiring clock redundancy
- Max. output skew of 250 ps (125 ps within one bank)
- Selectable output configurations per output bank
- Individually per-bank high-impedance tristate
- Output disable (stop in logic low state) control
- 48 ld LQFP package
- Ambient operating temperature range of  $-40$  to  $85^{\circ}\text{C}$

### Functional Description

The MPC9443 is a full static design supporting clock frequencies up to 350 MHz. The signals are generated and retimed on-chip to ensure minimal skew between the four output banks.

Two independent LVPECL compatible clock inputs are available. This feature supports redundant differential clock sources. In addition, the MPC9443 supports single-ended LVCMOS clock distribution systems. Each of the four output banks can be individually supplied by 2.5 V or 3.3 V, supporting mixed voltage applications. The FSELx pins choose between division of the input reference frequency by one or two. The frequency divider can be set individually for each output bank. The MPC9443 output banks are in high-impedance state by deasserting the  $\overline{\text{OE}}_N$  pins. Asserting  $\overline{\text{OE}}_N$  will enable output banks. Please see **Table 4. Output High-Impedance Control ( $\text{OE}_N$ )** for details. The outputs can be synchronously stopped (logic low state). The outputs provide LVCMOS compatible levels with the capability to drive terminated  $50\ \Omega$  transmission lines. For series terminated transmission lines, each of the MPC9443 outputs can drive one or two traces giving the devices an effective fanout of 1:32 at  $V_{\text{CC}} = 3.3\ \text{V}$ . The device is packaged in a  $7 \times 7\ \text{mm}^2$  48-lead LQFP package.

3.  $t_{sk(LH, HL)}$  includes both device skew referenced to the rising output edge and device skew referenced to the falling output edge.
4. Output pulse skew is the absolute difference of the propagation delay times:  $|t_{PLH} - t_{PHL}|$

APPLICATIONS INFORMATION

Driving Transmission Lines

The MPC9443 clock driver was designed to drive high speed signals in a terminated transmission line environment. To provide the optimum flexibility to the user the output drivers were designed to exhibit the lowest impedance possible. With an output impedance of less than 20 Ω the drivers can drive either parallel or series terminated transmission lines at  $V_{CC} = 3.3$  V. For more information on transmission lines the reader is referred to application note AN1091. In most high performance clock networks point-to-point distribution of signals is the method of choice. In a point-to-point scheme either series terminated or parallel terminated transmission lines can be used. The parallel technique terminates the signal at the end of the line with a 50 Ω resistance to  $V_{CC} \div 2$ .

This technique draws a fairly high level of DC current and thus only a single terminated line can be driven by each output of the MPC9443 clock driver. For the series terminated case however there is no DC current draw, thus the outputs can drive multiple series terminated lines. **Figure 3. Single versus Dual Transmission Lines** illustrates an output driving a single series terminated line versus two series terminated lines in parallel. When taken to its extreme the fanout of the MPC9443 clock driver is effectively doubled due to its capability to drive multiple lines (at  $V_{CC} = 3.3$  V).

Figure 3. Single versus Dual Transmission Lines

The waveform plots in **Figure 4. Single versus Dual Waveforms** show the simulation results of an output driving a single line versus two lines. In both cases the drive capability of the MPC9443 output buffer is more than sufficient to drive 50 Ω transmission lines on the incident edge. Note from the delay measurements in the simulations a delta of only 43 ps exists between the two differently loaded outputs. This suggests that the dual line driving need not be used exclusively to maintain the tight output-to-output skew of the MPC9443. The output waveform in **Figure 4. Single versus Dual Waveforms** shows a step in the waveform, this step is caused by the impedance mismatch seen looking into the driver. The parallel combination

of the 31 Ω series resistor plus the output impedance does not match the parallel combination of the line impedances. The voltage wave launched down the two lines will equal:

$$V_L = V_S (Z_0 \div (R_S + R_0 + Z_0))$$

$$Z_0 = 50 \Omega \parallel 50 \Omega$$

$$R_S = 31 \Omega \parallel 31 \Omega$$

$$R_0 = 19 \Omega$$

$$V_L = 3.0 (25 \div (15.5 + 19 + 25))$$

$$= 1.26V$$

At the load end the voltage will double, due to the near unity reflection coefficient, to 2.52 V. It will then increment towards the quiescent 3.0 V in steps separated by one round trip delay (in this case 4.0 ns).

Figure 4. Single versus Dual Waveforms

Since this step is well above the threshold region it will not cause any false clock triggering, however designers may be uncomfortable with unwanted reflections on the line. To better match the impedances when driving multiple lines the situation in **Figure 5. Optimized Dual Line Termination** should be used. In this case the series terminating resistors are reduced such that when the parallel combination is added to the output buffer impedance the line impedance is perfectly matched.

Figure 5. Optimized Dual Line Termination

### Power Consumption of the MPC9443 and Thermal Management

The MPC9443 AC specification is guaranteed for the entire operating frequency range up to 350 MHz. The MPC9443 power consumption and the associated long-term reliability may decrease the maximum frequency limit, depending on operating conditions such as clock frequency, supply voltage, output loading, ambient temperature, vertical convection and thermal conductivity of package and board. This section describes the impact of these parameters on the junction temperature and gives a guideline to estimate the MPC9443 die junction temperature and the associated device reliability. For a complete analysis of power consumption as a function of operating conditions and associated long term device reliability please refer to the application note AN1545. According the AN1545, the long-term device reliability is a function of the die junction temperature:

**Table 13. Die Junction Temperature and MTBF**

Junction Temperature (°C)	MTBF (Years)
100	20.4
110	9.1
120	4.2
130	2.0

Increased power consumption will increase the die junction temperature and impact the device reliability (MTBF). According to the system-defined tolerable MTBF, the die junction temperature of the MPC9443 needs to be controlled and the thermal impedance of the board/package should be optimized. The power dissipated in the MPC9443 is represented in equation 1.

Where  $I_{CCQ}$  is the static current consumption of the MPC9443,  $C_{PD}$  is the power dissipation capacitance per output,  $(M)\Sigma C_L$  represents the external capacitive output load, N is the number of active outputs (N is always 16 in case of the MPC9443). The MPC9443 supports driving transmission lines to maintain high signal integrity and tight timing parameters. Any transmission line will hide the lumped capacitive load at the end of the board trace, therefore,  $\Sigma C_L$  is zero for controlled transmission line systems and can be eliminated from equation 1. Using parallel termination output termination results in equation 2 for power dissipation.

$$P_{TOT} = [I_{CCQ} + V_{CC} \cdot f_{CLOCK} \cdot (N \cdot C_{PD} + \sum_M C_L)] \cdot V_{CC} \quad \text{Equation 1}$$

$$P_{TOT} = V_{CC} \cdot [I_{CCQ} + V_{CC} \cdot f_{CLOCK} \cdot (N \cdot C_{PD} + \sum_M C_L)] + \sum_P [DC_Q \cdot I_{OH} \cdot (V_{CC} - V_{OH}) + (1 - DC_Q) \cdot I_{OL} \cdot V_{OL}] \quad \text{Equation 2}$$

$$T_J = T_A + P_{TOT} \cdot R_{thja} \quad \text{Equation 3}$$

$$f_{CLOCK,MAX} = \frac{1}{C_{PD} \cdot N \cdot V_{CC}^2} \cdot \left[ \frac{T_{j,MAX} - T_A}{R_{thja}} - (I_{CCQ} \cdot V_{CC}) \right] \quad \text{Equation 4}$$

In equation 2, P stands for the number of outputs with a parallel or thevenin termination,  $V_{OL}$ ,  $I_{OL}$ ,  $V_{OH}$  and  $I_{OH}$  are a function of the output termination technique and  $DC_Q$  is the clock signal duty cycle. If transmission lines are used  $\Sigma C_L$  is zero in equation 2 and can be eliminated. In general, the use of controlled transmission line techniques eliminates the impact of the lumped capacitive loads at the end lines and greatly reduces the power dissipation of the device. Equation 3 describes the die junction temperature  $T_J$  as a function of the power consumption.

Where  $R_{thja}$  is the thermal impedance of the package (junction to ambient) and  $T_A$  is the ambient temperature. According to **Table 13**, the junction temperature can be used to estimate the long-term device reliability. Further, combining equation 1 and equation 2 results in a maximum operating frequency for the MPC9443 in a series terminated transmission line system.

$T_{J,MAX}$  should be selected according to the MTBF system requirements and **Table 13**.  $R_{thja}$  can be derived from Table 14. The  $R_{thja}$  represent data based on 1S2P boards, using 2S2P boards will result in a lower thermal impedance than indicated below.

**Table 14. Thermal Package Impedance of the 48 Id LQFP**

Convection, LFPM	$R_{thja}$ (1P2S board), K/W	$R_{thja}$ (2P2S board), K/W
Still air	69	53
100 lfpm		
200 lfpm	64	50
300 lfpm		
400 lfpm		
500 lfpm		

If the calculated maximum frequency is below 250 MHz, it becomes the upper clock speed limit for the given application conditions. The following eight derating charts describe the safe frequency operation range for the MPC9443. The charts were calculated for a maximum tolerable die junction temperature of 110°C (120°C), corresponding to an estimated MTBF of 9.1 years (4 years), a supply voltage of 3.3 V and series terminated transmission line or capacitive loading. Depending on a given set of these operating conditions and the available device convection a decision on the maximum operating frequency can be made.

NOTES:

1. DIMENSIONING AND TOLERANCING PER ASME Y14.5m, 1994.
2. CONTROLLING DIMENSION: MILLIMETER.
3. DATUM PLAN AB IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.
4. DATUMS T, U, AND Z TO BE DETERMINED AT DATUM PLANE AB.
5. DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE AC.
6. DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.250 PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE AB.
7. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. DAMBAR PROTRUSION SHALL NOT CAUSE THE D DIMENSION TO EXCEED 0.350.
8. MINIMUM SOLDER PLATE THICKNESS SHALL BE 0.0076.
9. EXACT SHAPE OF EACH CORNER IS OPTIONAL.

MILLIMETERS		
DIM	MIN	MAX
A	7.000	BSC
A1	3.500	BSC
