

FEATURES

Single-Channel, 24-Bit Σ - Δ ADC
 Pin Configurable (No Programmable Registers)
*ISOURCE Select*TM
 Pin Programmable Input Ranges (± 2.56 V or ± 160 mV)
 Fixed 19.79 Hz Update Rate
 Simultaneous 50 Hz and 60 Hz Rejection
 24-Bit No Missing Codes
 18.5-Bit p-p Resolution (± 2.56 V Range)
 16.5-Bit p-p Resolution (± 160 mV Range)

INTERFACE

Master or Slave Mode of Operation
 Slave Mode
 3-Wire Serial
 SPI[®], QSPITM, MICROWIRETM, and DSP-Compatible
 Schmitt Trigger on SCLK

POWER

Specified for Single 3 V and 5 V Operation
 Normal: 1.3 mA @ 3 V
 Power-Down: 9 μ A

ON-CHIP FUNCTIONS

Rail-to-Rail Input Buffer and PGA

APPLICATIONS

Sensor Measurement
 Industrial Process Control
 Temperature Measurement
 Pressure Measurement
 Weigh Scales
 Portable Instrumentation

GENERAL DESCRIPTION

The AD7783 is a complete analog front end for low frequency measurement applications. The 24-bit sigma-delta ADC contains one fully differential input channel that can be configured with a gain of 1 or 16 allowing full-scale input signal ranges of ± 2.56 V or ± 160 mV from a +2.5 V differential reference input. It also contains two 200 μ A integrated current sources.

The AD7783 has an extremely simple, read-only digital interface that can be operated in master mode or slave mode. There are no on-chip registers to be programmed. The input signal range and current source selection are configured using two external pins.

REV. B

FUNCTIONAL BLOCK DIAGRAM

BASIC CONNECTION DIAGRAM

The device operates from a 32.768 kHz crystal with an on-chip PLL generating the required internal operating frequency. The output data rate from the part is fixed via the master clock at 19.79 Hz and provides simultaneous 50 Hz and 60 Hz rejection at this update rate. At this update rate, 18-bit p-p resolution can be obtained.

The part operates from a single 3 V or 5 V supply. When operating from 3 V supplies, the power dissipation for the part is 3.9 mW. The AD7783 is available in a 16-lead TSSOP.

Another part in the AD778x family is the AD7782. It is similar to the AD7783 except it has no integrated current sources and two differential input channels.

AD7783—SPECIFICATIONS¹ (V_{DD} = 2.7 V to 3.6 V or 4.75 V to 5.25 V, REFIN(+) = 2.5 V; REFIN(-) = GND; GND = 0 V; XTAL1/XTAL2 = 32.768 kHz Crystal; all specifications T_{MIN} to T_{MAX}, unless otherwise noted.)

NOTES

¹Sample tested during initial release to ensure compliance. All input signals are specified with $t_R = t_F = 5\text{ ns}$ (10% to 90% of V_{DD}) and timed from a voltage level of 1.6 V.

²See Figure 2.

³These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross the V_{OL} or V_{OH} limits.

⁴SCLK active edge is falling edge of SCLK.

⁵These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 50 pF capacitor. This means the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7783 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION

PIN FUNCTION DESCRIPTIONS

Pin No.	Mnemonic	Function
1	XTAL1	Input to the 32.768 kHz Crystal Oscillator Inverter.
2	REFIN(+)	Positive Reference Input. REFIN(+) can lie anywhere between V_{DD} and $GND + 1 V$. The nominal reference voltage ($REFIN(+) - REFIN(-)$) is 2.5 V, but the part functions with a reference from 1 V to V_{DD} .
3	REFIN(-)	Negative Reference Input. This reference input can lie anywhere between GND and $V_{DD} - 1 V$.
4	AIN(+)	Analog Input. AIN(+) is the positive terminal of the fully differential analog input pair AIN(+)/AIN(-).
5	AIN(-)	Analog Input. AIN(-) is the negative terminal of the fully differential analog input pair AIN(+)/AIN(-).
6	IOUT1	Output from Internal 200 μA Excitation Current Source. Either current source IEXC1 or IEXC2 can be switched to this output using hardware control pin IPIN.
7	IOUT2	Output from Internal 200 μA Excitation Current Source. Either current source IEXC1 or IEXC2 can be switched to this output using hardware control pin IPIN.
8	IPIN	Logic Input that Selects the Routing of the On-Chip Current Sources. When IPIN is tied to GND , IEXC1 is routed to IOUT1 and IEXC2 is routed to IOUT2. When IPIN is tied to V_{DD} , IEXC1 is routed to IOUT2 and IEXC2 is routed to IOUT1.
9	RANGE	Logic Input that Configures the Input Range on the Internal PGA. With $RANGE = 0$, the full-scale input range is $\pm 160 mV$; the full-scale input range equals $\pm 2.56 V$ when $RANGE = 1$ for a 2.5 V reference.
10	SCLK	Serial Clock Input/Output for Data Transfers from the ADC. When the device is operated in master mode, SCLK is an output with one SCLK period equal to one XTAL period. In slave mode, SCLK is generated by an external source. In slave mode, all the data can be transmitted on a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted from the AD7783 in smaller batches of data. SCLK is Schmitt triggered (slave mode), making the interface suitable for opto-isolated applications.
11	\overline{CS}	Chip Select Input. \overline{CS} is an active low logic input used to select the AD7783. When \overline{CS} is low, the PLL establishes lock and allows the AD7783 to initiate a conversion. When \overline{CS} is high, the conversion is aborted, DOUT and SCLK are three-stated, the AD7783 enters standby mode, and any conversion result in the output shift register is lost.
12	DOUT/ \overline{RDY}	Serial Data Output/Data Ready Output. DOUT/ \overline{RDY} serves a dual purpose in this interface. When a conversion is initiated, DOUT/ \overline{RDY} goes high and remains high until the conversion is complete. DOUT/ \overline{RDY} will then return low to indicate that valid data is available to be read from the device. In slave mode, this acts as an interrupt to the processor, indicating that valid data is available. If data is not read after a conversion, DOUT/ \overline{RDY} will go high before the next update occurs. In master mode, DOUT/ \overline{RDY} goes low for at least half an SCLK cycle before the device produces SCLKs. When SCLK becomes active, data is output on the DOUT/ \overline{RDY} pin. Data is output on the falling SCLK edge and is valid on the rising edge.
13	MODE	The MODE pin selects master or slave mode of operation. When $MODE = 0$, the AD7783 operates in master mode; the AD7783 is configured for slave mode when $MODE = 1$.
14	GND	Ground Reference Point for the AD7783.
15	V_{DD}	Supply Voltage, 3 V or 5 V Nominal.
16	XTAL2	Output from the 32.768 kHz Crystal Oscillator Inverter.

Typical Performance Characteristics—AD7783

TPC 2. RMS Noise vs. Reference Input

ADC CIRCUIT INFORMATION

Overview

The AD7783 incorporates a Σ - Δ ADC channel, on-chip programmable gain amplifier, and on-chip digital filtering intended for the measurement of wide dynamic range, low frequency signals such as those in weigh-scale, strain gage, pressure transducer, or temperature measurement applications.

This ADC input is buffered and can be programmed to have an input voltage range of ± 160 mV or ± 2.56 V. The input channel is configured as a fully differential input. Buffering the input channel means that the part can accommodate significant source impedances on the analog input and that R, C filtering (for noise rejection or RFI reduction) can be placed on the analog input if required. The device requires an external reference of 2.5 V nominal. Figure 3 shows the basic connections required to operate the part.

Figure 3. Basic Connection Diagram

The output rate of the AD7783 (f_{ADC}) equals

$$f_{ADC} = 32.768 \times 10^3 / (69 \times 8 \times 3)$$

while the settling time equals

$$t_{SETTLE} = \left(\frac{2}{f_{ADC}} \right) = 2 \times t_{ADC}$$

Normal-mode rejection is the major function of the digital filter on the AD7783. Simultaneous 50 Hz and 60 Hz rejection of better than 60 dB is achieved as notches are placed at both 50 Hz and 60 Hz. Figure 4 shows the filter rejection.

Figure 4. Filter Profile (Filter Notches at Both 50 Hz and 60 Hz)

AD7783

NOISE PERFORMANCE

Table I shows the output rms noise and output peak-to-peak resolution in bits (rounded to the nearest 0.5 LSB) for the two input voltage ranges. The numbers are typical and are generated at a differential input voltage of 0 V. The peak-to-peak resolution figures represent the resolution for which there will be no code flicker within a six-sigma limit. The output noise comes from two sources. The first is the electrical noise in the semiconductor devices (device noise) used in the implementation of the modulator. Secondly, when the analog input is converted into the digital domain, quantization noise is added. The device noise is at a low level and is independent of frequency. The quantization noise starts at an even lower level but rises rapidly with increasing frequency to become the dominant noise source.

Table I. Typical Output RMS Noise and Peak-to-Peak Resolution vs. Input Range

	Input Range	
	± 160 mV	± 2.56 V
Noise (μ V)	0.65	2.30
Peak-to-Peak Resolution (Bits)	16.5	18.5

DIGITAL INTERFACE

The AD7783's serial interface consists of four signals: \overline{CS} , SCLK, DOUT/RDY, and MODE. The MODE pin is used to select the master/slave mode of operation. When the part is configured as a master, SCLK is an output; SCLK is an input when slave mode is selected. Data transfers take place with respect to this SCLK signal. The DOUT/RDY line is used for accessing data from the data register. This pin also functions as a RDY line. When a conversion is complete, DOUT/RDY goes low to indicate that data is ready to be read from the AD7783's data register. It is reset high when a read operation from the data register is complete. It also goes high prior to the updating of the output register to indicate when *not* to read from the device to ensure that a data read is not attempted while the register is being updated. The digital conversion is also output on this pin.

\overline{CS} is used to select the device and to place the device in standby mode. When \overline{CS} is taken low, the AD7783 is powered up, the PLL locks, and the device initiates a conversion. The device will continue to convert until \overline{CS} is taken high. When \overline{CS} is taken high, the AD7783 is placed in standby mode, minimizing the current consumption. The conversion is aborted, DOUT and SCLK are three-stated, and the result in the data register is lost.

Figure 2 shows the timing diagram for interfacing to the AD7783 with \overline{CS} used to decode the part.

MASTER MODE (MODE = 0)

In this mode, SCLK is provided by the AD7783. With \overline{CS} low, SCLK becomes active when a conversion is complete and generates 24 falling and rising edges. The DOUT/RDY pin, which is normally high, goes low to indicate that a conversion is complete. Data is output on the DOUT/RDY pin following the SCLK falling edge and is valid on the SCLK rising edge. When the 24-bit word has been output, SCLK idles high until the next conversion is complete. DOUT/RDY returns high and will remain high until another conversion is available. It then operates as a RDY signal again. The part will continue to convert until \overline{CS} is taken high. SCLK and DOUT/RDY are three-stated when \overline{CS} is taken high.

SLAVE MODE (MODE = 1)

In slave mode, the SCLK is generated externally. SCLK must idle high between data transfers. With \overline{CS} low, DOUT/RDY goes low when a conversion is complete. Twenty-four SCLK pulses are needed to transfer the digital word from the AD7783. Twenty-four consecutive pulses can be generated or, alternatively, the data transfer can be split into batches. This is useful when interfacing to a microcontroller that uses 8-bit transfers. Data is output following the SCLK falling edge and is valid on the SCLK rising edge.

CIRCUIT DESCRIPTION

Analog Input Channel

The ADC has one fully differential input channel. It feeds into a high impedance input stage of the buffer amplifier. As a result, the ADC input can handle significant source impedances and is tailored for direct connection to external resistive-type sensors, such as strain gages or resistance temperature detectors (RTDs).

The absolute input voltage range on the ADC input is restricted to a range between $GND + 100$ mV and $V_{DD} - 100$ mV. Care must be taken in setting up the common-mode voltage and input voltage range so that these limits are not exceeded; otherwise, there will be a degradation in linearity and noise performance.

Programmable Gain Amplifier

The output from the buffer on the ADC is applied to the input of the on-chip programmable gain amplifier (PGA). The PGA gain range is programmed via the RANGE pin. With an external 2.5 V reference applied, the PGA can be programmed to have a bipolar range of ± 160 mV (RANGE = 0) or ± 2.56 V (RANGE = 1). These are the ranges that should appear at the input to the on-chip PGA.

Bipolar Configuration/Output Coding

The analog input on the AD7783 accepts bipolar input voltage ranges. Signals on the AIN(+) input of the ADC are referenced

to the voltage on the AIN(-) input. For example, if AIN(-) is 2.5 V and the AD7783 is configured for an analog input range of ± 160 mV, the analog input range on the AIN(+) input is 2.34 V to 2.66 V (i.e., $2.5 \text{ V} \pm 0.16 \text{ V}$).

The coding is offset binary with a negative full-scale voltage resulting in a code of 000 . . . 000, a zero differential voltage resulting in a code of 100 . . . 000, and a positive full-scale voltage resulting in a code of 111 . . . 111. The output code for any analog input voltage can be represented as follows:

$$\text{Code} = 2^{N-1} \times \left[\left(\text{AIN} \times \text{GAIN} / (1.024 \times V_{\text{REF}}) \right) + 1 \right]$$

where AIN is the analog input voltage, GAIN is the PGA gain, i.e., 1 on the ± 2.56 V range and 16 on the ± 160 mV range, and $N = 24$.

Excitation Currents

The AD7783 also contains two matched 200 μA constant current sources. Both source current from V_{DD} that is directed to either the IOUT1 or IOUT2 pins of the device depending on the polarity of the IPIN pin. These current sources can be used to excite external resistive bridge or RTD sensors.

Crystal Oscillator

The AD7783 is intended for use with a 32.768 kHz watch crystal. A PLL internally locks onto a multiple of this frequency to provide a stable 4.194304 MHz clock for the ADC. The modulator sample rate is the same as the crystal oscillator frequency. The start-up time associated with 32.768 kHz crystals is typically 300 ms. In some cases, it will be necessary to connect capacitors on the crystal to ensure that it does not oscillate at overtones of its fundamental operating frequency. The values of capacitors will vary depending on the manufacturer's specifications.

Reference Input

The AD7783 has a fully differential reference input capability for the channel. The common-mode range for differential inputs is from GND to V_{DD} . The reference input is unbuffered, and therefore excessive R-C source impedances will introduce gain errors. The reference voltage REF_{IN} (REF_{IN}(+) - REF_{IN}(-)) is 2.5 V nominal for specified operation, but the AD7783 is functional with reference voltages from 1 V to V_{DD} . In applications where the excitation (voltage or current) for the transducer on the analog input also drives the reference voltage for the part, the effect of the low frequency noise in the excitation source will be removed as the application is ratiometric. If the AD7783 is used in a nonratiometric application, a low noise reference should be used. Recommended reference voltage sources for the AD7783 include the AD780, REF43, and REF192. It should also be noted that the reference inputs provide a high impedance, dynamic load. Because the input impedance of each reference input is dynamic, resistor/capacitor combinations on these inputs can cause dc gain errors, depending on the output impedance of the source that is driving the reference inputs. Recommended reference voltage sources (e.g., AD780) will typically have low output impedances and are, therefore, tolerant to having decoupling capacitors on the REF_{IN}(+) without introducing gain errors in the system.

Deriving the reference input voltage across an external resistor will mean that the reference input sees a significant external source impedance. External decoupling on the REF_{IN} pins would not be recommended in this type of circuit configuration.

Grounding and Layout

Since the analog inputs and reference inputs on the ADC are differential, most of the voltages in the analog modulator are common-mode voltages. The excellent common-mode rejection of the part will remove common-mode noise on these inputs. The digital filter will provide rejection of broadband noise on the power supply, except at integer multiples of the modulator sampling frequency. The digital filter also removes noise from the analog and reference inputs, provided these noise sources do not saturate the analog modulator. As a result, the AD7783 is more immune to noise interference than a conventional high resolution converter. However, because the resolution of the AD7783 is so high, and the noise levels from the AD7783 are so low, care must be taken with regard to grounding and layout. The printed circuit board that houses the AD7783 should be designed such that the analog and digital sections are separated and confined to certain areas of the board. A minimum etch technique is generally best for ground planes as it gives the best shielding.

It is recommended that the AD7783's GND pin be tied to the AGND plane of the system. In any layout, it is important that the user keep in mind the flow of currents in the system, ensuring that the return paths for all currents are as close as possible to the paths the currents took to reach their destinations. Avoid forcing digital currents to flow through the AGND sections of the layout.

The AD7783's ground plane should be allowed to run under the AD7783 to prevent noise coupling. The power supply lines to the AD7783 should use as wide a trace as possible to provide low impedance paths and reduce the effects of glitches on the power supply line. Fast switching signals like clocks should be shielded with digital ground to avoid radiating noise to other sections of the board, and clock signals should never be run near the analog inputs. Avoid crossover of digital and analog signals. Traces on opposite sides of the board should run at right angles to each other. This will reduce the effects of feedthrough through the board. A microstrip technique is by far the best but is not always possible with a double-sided board. In this technique, the component side of the board is dedicated to ground planes while signals are placed on the solder side.

Good decoupling is important when using high resolution ADCs. V_{DD} should be decoupled with 10 μF tantalum in parallel with 0.1 μF capacitors to GND. To achieve the best from these decoupling components, they have to be placed as close as possible to the device, ideally right up against the device. All logic chips should be decoupled with 0.1 μF ceramic capacitors to DGND.

OUTLINE DIMENSIONS

16-Lead Thin Shrink Small Outline Package [TSSOP] (RU-16)

Dimensions shown in millimeters

COMPLIANT TO JEDEC STANDARDS MS-153AB
