## Compact $+30 \mathrm{~V} / \pm 15 \mathrm{~V} 256$-Position Digital Potentiometer

## FEATURES

256 position
$10 \mathrm{k} \Omega, 50 \mathrm{k} \Omega, 100 \mathrm{k} \Omega$
+20 V to +30 V single-supply operation
$\pm 10 \mathrm{~V}$ to $\pm 15 \mathrm{~V}$ dual-supply operation
3-wire SP1®-compatible serial interface
Low temperature coefficient 35 ppm $/{ }^{\circ} \mathrm{C}$ typical
THD 0.006\% typical
Midscale preset
Compact MSOP-10 package
Automotive temperature range: $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
iCMOS ${ }^{\text {TM1 }}$ process technology

## APPLICATIONS

## High voltage DAC

Programmable power supply
Programmable gain and offset adjustment
Programmable filters and delays
Actuator control
Audio volume control
Mechanical potentiometer replacement

## GENERAL DESCRIPTION

The AD5290 is one of the few high voltage, high performance, and compact digital potentiometers ${ }^{2,3}$ in the market at present. This device can be used as a programmable resistor or resistor divider. The AD5290 performs the same electronic adjustment function as mechanical potentiometers, variable resistors, and trimmers, with enhanced resolution, solid-state reliability, and superior temperature stability.

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.

With digital rather than manual control, the AD5290 provides layout flexibility and allows closed-loop dynamic controllability.

The AD5290 is available in MSOP-10 package and has $10 \mathrm{k} \Omega$, $50 \mathrm{k} \Omega$, and $100 \mathrm{k} \Omega$ options. All parts are guaranteed to operate over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ extended automotive temperature range.

| Bandwidth -3 dB | BW | Code $=0 \times 80$ |  | 470 |  | kHz |
| Total Harmonic Distortion | THDw | $\mathrm{V}_{\mathrm{A}}=1 \mathrm{Vrms}, \mathrm{V}_{\mathrm{B}}=0 \mathrm{~V}, \mathrm{f}=1 \mathrm{kHz}$ |  | 0.006 |  | \% |
| Vw Settling Time | $\mathrm{ts}^{\text {s}}$ | $\mathrm{V}_{\mathrm{A}}=10 \mathrm{~V}, \mathrm{~V}_{\mathrm{B}}=0 \mathrm{~V}, \pm 1 \mathrm{LSB}$ error band |  | 4 |  | $\mu \mathrm{s}$ |
| Resistor Noise Voltage | en_wb | $\mathrm{Rw}_{\mathrm{w}}=5 \mathrm{k} \Omega, \mathrm{f}=1 \mathrm{kHz}$ |  | 9 |  | $\mathrm{nV} / \sqrt{ } \mathrm{Hz}$ |

${ }^{1}$ Typical represents average reading at $+25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{DD}}=+15 \mathrm{~V}$, and $\mathrm{V}_{S S}=-15 \mathrm{~V}$.
${ }^{2}$ Resistor position nonlinearity error R-INL is the deviation from an ideal value measured between the maximum resistance and the minimum resistance wiper positions. R-DNL measures the relative step change from an ideal value measured between successive tap positions. Parts are guaranteed monotonic.
${ }^{3}$ All parts have a $35 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ temperature coefficient.
${ }^{4}$ INL and DNL are measured at $\mathrm{V}_{\mathrm{W}}$ with the RDAC configured as a potentiometer divider similar to a voltage output $D A C . V_{A}=V_{D D}$ and $V_{B}=0 \mathrm{~V}$. DNL specification limits of $\pm 1$ LSB maximum are guaranteed monotonic operating conditions.
${ }^{5}$ Resistor Terminal A, Terminal B, and Terminal W have no limitations on polarity with respect to each other.
${ }^{6}$ Guaranteed by design and not subject to production test.
${ }^{7} \mathrm{P}_{\mathrm{DISS}}$ is calculated from ( $\mathrm{l}_{\mathrm{DD}} \times \mathrm{V}_{D D}$ ) $+\mathrm{abs}\left(\mathrm{l}_{S S} \times \mathrm{V}_{S S}\right)$. CMOS logic-level inputs result in minimum power dissipation.
${ }^{8}$ Bandwidth, noise, and settling times are dependent on the terminal resistance value chosen. The lowest $R$ value results in the fastest settling time and highest bandwidth. The highest R value results in the minimum overall power consumption.
${ }^{9}$ All dynamic characteristics use $V_{D D}=+15 \mathrm{~V}$ and $\mathrm{V}_{\mathrm{SS}}=-15 \mathrm{~V}$.

| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Maximum Junction Temperature ( $\mathrm{T}_{\text {max }}{ }^{2}$ | $+150^{\circ} \mathrm{C}$ |
| Storage Temperature | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 sec to 30 sec ) | $245^{\circ} \mathrm{C}$ |
| Thermal Resistance ${ }^{2} \theta_{\text {Ja: }}$ : MSOP-10 | $230^{\circ} \mathrm{C} / \mathrm{W}$ |

[^2]Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATION AND DESCRIPTIONS

Figure 4. AD5290 Pin Configuration
Table 6. AD5290 Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :--- | :--- | :--- |
| 1 | A | A Terminal. $\mathrm{V}_{S S} \leq \mathrm{V}_{\mathrm{A}} \leq \mathrm{V}_{\mathrm{DD}}$. |
| 2 | B | B Terminal. $\mathrm{V}_{\mathrm{SS}} \leq \mathrm{V}_{\mathrm{B}} \leq \mathrm{V}_{\mathrm{DD}}$. |
| 3 | V $_{\mathrm{SS}}$ | Negative Supply. Connect to 0 V for single-supply applications. |
| 4 | GND | Digital Ground. |
| 5 | $\overline{\mathrm{CS}}$ | Chip Select Input; Active Low. When $\overline{\mathrm{CS}}$ returns high, data is loaded into the wiper register. |
| 6 | CLK | Serial Clock Input. Positive edge triggered. |
| 7 | SDI | Serial Data Input Pin. Shifts in one bit at a time on positive clock CLK edges. MSB loaded first. |
| 8 | SDO | Serial Data Output Pin. Internal N-Ch FET with open-drain output that requires external pull-up resistor. |
| 9 | It shifts out the previous eight SDI bits that allow daisy-chain operation of multiple packages. |  |
| 10 | W | Positive Power Supply. |

## THEORY OF OPERATION

## PROGRAMMING THE VARIABLE RESISTOR

## Rheostat Operation

The part operates in the rheostat mode when only two terminals are used as a variable resistor. The unused terminal can be floating or tied to the W terminal as shown in Figure 26.

Figure 26. Rheostat Mode Configuration
The nominal resistance between Terminal A and Terminal B, $\mathrm{R}_{A B}$, is available in $10 \mathrm{k} \Omega, 50 \mathrm{k} \Omega$, and $100 \mathrm{k} \Omega$ with $\pm 30 \%$ tolerance and has 256 tap points accessed by the wiper terminal. The 8-bit data in the RDAC latch is decoded to select one of the 256 possible settings. Figure 27 shows a simplified RDAC structure.

Figure 27. AD5290 Simplified RDAC Circuit.
( $R_{S}=$ Step Resistor, $R_{w}=$ Wiper Resistor)
In order to achieve optimum cost performance, Analog Devices has patented the RDAC segmentation architecture for all the digital potentiometers. In particular, the AD5290 employs a 3 -stage segmentation approach as shown in Figure 27. As a result, the general equation determining the digitally programmed output resistance between the W terminal and $B$ terminal is

$$
\begin{equation*}
R_{W B}(D)=\frac{D}{256} \times R_{A B}+3 \times R_{W} \tag{1}
\end{equation*}
$$

where:
$D$ is the decimal equivalent of the binary code loaded in the 8 -bit RDAC register from 0 to 255 .
$R_{A B}$ is the end-to-end resistance.
$R_{W}$ is one of the wiper resistances contributed by the on resistance of an internal switch.

The AD5290 wiper switch is designed with the transmission gate CMOS topology and with the gate voltage derived from $\mathrm{V}_{\mathrm{DD}}$. The wiper resistance, RW, is a function of $\mathrm{V}_{\mathrm{DD}}$ and temperature. Contrary to the temperature coefficient of the $\mathrm{R}_{A B}$, which is only $35 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$, the temperature coefficient of the wiper resistance is significantly higher because the wiper resistance doubles from $25^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$. As a result, the user must take into consideration the contribution of RW on the desirable resistance. On the other hand, the wiper resistance is insensitive to the tap point potential. As a result, RW remains relatively flat at a given $V_{D D}$ and temperature at various codes.

Assuming that an ideal $10 \mathrm{k} \Omega$ part is used, the wiper's first connection starts at the B terminal for the programming code of $0 \times 00$ where SWB is closed. The minimum resistance between Terminal W and Terminal B is, therefore, generally $150 \Omega$. The second connection is the first tap point, which corresponds to $189 \Omega\left(R_{W B}=1 / 256 \times R_{A B}+3 R_{W}=39 \Omega+150 \Omega\right)$ for code $0 \times 01$, and so on. Each LSB data value increase moves the wiper up the resistor ladder until the last tap point is reached at $10,110 \Omega$.

In the zero-scale condition, a finite total wiper resistance of $150 \Omega$ is present. Regardless of which setting the part is operating in, care should be taken to limit the current between the A terminal to B terminal, W terminal to A terminal, and W terminal to B terminal, to the maximum dc current of 5 mA or pulse current of 20 mA . Otherwise, degradation, or possible destruction of the internal switch contact, can occur.

Similar to the mechanical potentiometer, the resistance of the RDAC between the W terminal and the A terminal also produces a digitally controlled complementary resistance, R $\mathrm{R}_{\mathrm{wA}}$. $\mathrm{R}_{\mathrm{WA}}$ starts at the maximum resistance value and decreases as the data loaded into the latch increases. The general equation for this operation is

$$
\begin{equation*}
R_{W A}(D)=\frac{256-D}{256} \times R_{A B}+3 \times R_{W} \tag{2}
\end{equation*}
$$

## PROGRAMMING THE POTENTIOMETER DIVIDER

## Voltage Output Operation

The digital potentiometer easily generates a voltage divider at wiper to B and wiper to A proportional to the input voltage at A to B . Unlike the polarity of $\mathrm{V}_{\mathrm{DD}}$ to GND, which must be positive, voltage across $A$ to $B, W$ to $A$, and $W$ to $B$ can be at either polarity.

Figure 28. Potentiometer Mode Configuration
If ignoring the effect of the wiper resistance for simplicity, connecting the A terminal to 30 V and the B terminal to ground produces an output voltage at the Wiper W to Terminal B ranging from 0 V to 1 LSB less than 30 V . Each LSB of voltage is equal to the voltage applied across Terminal A and Terminal B, divided by the 256 positions of the potentiometer divider. The general equation defining the output voltage at $\mathrm{V}_{\mathrm{w}}$ with respect to ground for any valid input voltage applied to Terminal A and Terminal B is

$$
\begin{equation*}
V_{W}(D)=\frac{D}{256} \times V_{A}+\frac{256-D}{256} \times V_{B} \tag{3}
\end{equation*}
$$

Operation of the digital potentiometer in the divider mode results in a more accurate operation over temperature. Unlike the rheostat mode, the output voltage is dependent mainly on the ratio of the internal resistors $\mathrm{R}_{\mathrm{WA}}$ and $\mathrm{R}_{\mathrm{WB}}$ and not the absolute values. Therefore, the temperature drift reduces to $5 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$.

## 3-WIRE SERIAL BUS DIGITAL INTERFACE

The AD5290 contains a 3-wire digital interface ( $\overline{\mathrm{CS}}, \mathrm{CLK}$, and SDI). The 8 -bit serial word must be loaded MSB first. The format of the word is shown in Table 4. The positive edge sensitive CLK input requires clean transitions to avoid clocking incorrect data into the serial input register. Standard logic families work well. When $\overline{\mathrm{CS}}$ is low, the clock loads data into the serial register on each positive clock edge.

The data setup and data hold times in the Specifications section determine the valid timing requirements. The AD5290 uses an 8 -bit serial input data register word that is transferred to the internal RDAC register when the $\overline{\mathrm{CS}}$ line returns to logic high. Extra MSB bits are ignored.

## DAISY CHAIN OPERATION

SDO shifts out the SDI content in the previous frame; thus it can be used for daisy-chaining multiple devices. The SDO pin contains an open drain N-Ch MOSFET and requires a pullup resistor if the SDO function is used. Users need to tie the SDO pin of one package to the SDI pin of the next package. Users may need to increase the clock period because the pull-up resistor and the capacitive loading at the SDO to SDI interface can induce time delay to the subsequent devices.

For example, in Figure 29, if two AD5290s are daisy-chained, a total of 16 bits of data are required for each operation. The first set of eight bits goes to U 2 , and the second set of eight bits goes to U1. The $\overline{\mathrm{CS}}$ should be kept low until all 16 bits are clocked into their respective serial registers. The $\overline{\mathrm{CS}}$ is then pulled high to complete the operation.

Figure 29. Daisy Chain Configuration

## ESD PROTECTION

All digital inputs are protected with a series input resistor and a Zener ESD structure, as shown in Figure 30. These structures apply to digital input pins, Pin $\overline{\mathrm{CS}}$, Pin CLK, Pin SDI, and Pin SDO.

Figure 30. Equivalent ESD Protection Circuit
All analog terminals are also protected by Zener ESD protection diodes, as shown in Figure 31.

Figure 31. Equivalent ESD Protection Analog Pins

## TERMINAL VOLTAGE OPERATING RANGE

The AD5290 V VD $_{\text {an }}$ and ss power supplies define the boundary conditions for proper 3-terminal digital potentiometer operation. The AD5290 can operate in single supply from +4.5 V to +33 V or dual supply from $\pm 4.5 \mathrm{~V}$ to $\pm 16.5 \mathrm{~V}$. The AD5290 is functional at low supply voltages such as 4.5 V , but the performance parameters are not guaranteed.

The voltages present on Terminal A, Terminal B, and Terminal W that are more positive than $V_{D D}$ or more negative than $V_{S S}$ are clamped by the internal forward-biased diodes (Figure 31).

## POWER-UP AND POWER-DOWN SEQUENCES

Because of the ESD protection diodes that limit the voltage compliance at Terminal A, Terminal B, and Terminal W (Figure 31), it is important to power $\mathrm{V}_{\mathrm{DD}} / \mathrm{V}_{\mathrm{SS}}$ before applying any voltage to Terminal A, Terminal B, and Terminal W. Otherwise, the diodes are forward-biased such that $\mathrm{V}_{\mathrm{DD}} / \mathrm{V}_{\text {Ss }}$ are powered unintentionally and affect the system. Similarly, $\mathrm{V}_{\mathrm{DD}} / \mathrm{V}_{\mathrm{SS}}$ should be powered down last. The ideal power-up sequence is as follows: GND, $\mathrm{V}_{\mathrm{DD}}, \mathrm{V}_{\text {SS }}$, digital inputs, and $\mathrm{V}_{\mathrm{A}} / \mathrm{V}_{\mathrm{B}} / \mathrm{V}_{\mathrm{W}}$. The order of powering $\mathrm{V}_{\mathrm{A}}, \mathrm{V}_{\mathrm{B}}, \mathrm{V}_{\mathrm{W}}$, and the digital inputs is not important, as long as they are powered after $\mathrm{V}_{\mathrm{DD}} / \mathrm{V}_{\mathrm{Ss}}$.

## LAYOUT AND POWER SUPPLY BIASING

It is good practice to use a compact, minimum lead-length layout design. The leads to the input should be as direct as possible, with a minimum conductor length. Ground paths should have low resistance and low inductance.

Similarly, it is also good practice to bypass the power supplies with quality capacitors. Low equivalent series resistance (ESR), $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ tantalum or electrolytic capacitors, should be applied at the supplies to minimize any transient disturbance and to filter low frequency ripple. Figure 32 illustrates the basic supply-bypassing configuration for the AD5290.

The ground pin of the AD5290 is a digital ground reference. To minimize the digital ground bounce, the AD5290 digital ground terminal should be joined remotely to the analog ground (Figure 32).

Figure 32. Power Supply Bypassing

## APPLICATIONS

## HIGH VOLTAGE DAC

AD5290 can be configured as a high voltage DAC, with output voltage as high as 30 V . The circuit is shown in Figure 33. The output is

$$
\begin{equation*}
V_{O}(D)=\frac{D}{256} \times\left[1.2 \mathrm{~V} \times\left(1+\frac{R_{2}}{R_{1}}\right)\right] \tag{4}
\end{equation*}
$$

where $D$ is the decimal code from 0 to 255 .

Figure 33. High Voltage DAC

## PROGRAMMABLE POWER SUPPLY

With a boost regulator, such as ADP1611, AD5290 can be used as the variable resistor at the regulator's FB pin to provide the programmable power supply (Figure 34). The output is

$$
\begin{equation*}
V_{O}=1.23 \mathrm{~V} \times\left[1+\frac{(\mathrm{D} / 256)-R_{A B}}{R_{2}}\right] \tag{5}
\end{equation*}
$$

AD5290's $V_{\text {DD }}$ is derived from the output. Initially, L1 acts as a short, and $V_{D D}$ is one diode voltage drop below +5 V . The output slowly establishes the final value.

Figure 34. Programmable Power Supply

## AUDIO VOLUME CONTROL

Because of its good THD performance and high voltage capability, AD5290 can be used as a digital volume control. If AD5290 is used directly as an audio attenuator or gain amplifier, a large step change in the volume level at any arbitrary time can lead to an abrupt discontinuity of the audio signal causing an audible zipper noise. To prevent this, a zerocrossing window detector can be inserted to the $\overline{\mathrm{CS}}$ line to delay the device update until the audio signal crosses the window. Since the input signal can operate on top of any dc level rather than absolute zero volt level, zero-crossing in this case means the signal is ac-coupled, and the dc offset level is the signal zero reference point.

The configuration to reduce zipper noise (Figure 35) and the results of using this configuration are shown in Figure 36. The input is ac-coupled by C 1 and attenuated down before feeding into the window comparator formed by U2, U3, and U4B (Figure 35). $\mathrm{U}_{6}$ is used to establish the signal zero reference. The upper limit of the comparator is set above its offset and, therefore, the output pulses high whenever the input falls between 2.502 V and 2.497 V (or 0.005 V window) in this example. This output is AND'ed with the chip select signal such that the AD5290 updates whenever the signal crosses the window. To avoid a constant update of the device, the chip select signal should be programmed as two pulses, rather than as one shown in Figure 36.

In Figure 35, the lower trace shows that the volume level changes from a quarter-scale to full-scale when a signal change occurs near the zero-crossing window.
