
Features

- ARM7TDMI® ARM® Thumb® Processor Core
- Two 16-bit Fixed-point OakDSPCore® Cores
- 256 x 32-bit Boot ROM
- 88K Bytes of Integrated Fast RAM for Each DSP
- Flexible External Bus Interface with Programmable Chip Selects
- Dual Codec Interface
- Multi-level Priority, Individually Maskable, Vectored Interrupt Controller
- Three 16-bit Timers/Counters
- Additional Watchdog Timer
- Two USARTs with FIFO and Modem Control Lines
- Industry Standard Serial Peripheral Interface (SPI)
- Up to 23 General-purpose I/O Pins
- On-chip DRAM Controller
- JTAG Debug Interface
- Software Development Suites Available for ARM7TDMI and OakDSPCore
- Supported by a Wide Range of Ready-to-use Application Software, including Multitasking Operating System, Networking, Modems and Voice Processing Functions
- Available in 160-lead PQFP Package
- 3.3V Power Supply

Description

The Atmel AT75C310 Smart Internet Appliance Processor (SIAP) is a high-performance processor specially designed for Internet appliance applications, such as Internet telephony (Voice-over-Internet Protocol – VoIP). The AT75C310 is built around an ARM7TDMI microcontroller core running at 20 MIPS with two DSP co-processors running at 40 MIPS each – all three processors delivering unmatched performance for low power consumption.

In a typical standalone VoIP phone, one DSP handles the voice processing functions (voice compression, acoustic echo cancellation, etc.), while the other one deals with the telephony functions (dialing, line echo cancellation, callerID detection, high-speed modem, etc.). In such an application, the power of the ARM7TDMI allows it to run the VoIP protocol stack as well as all the system control tasks.

Atmel provides the AT75C310 with three levels of software modules:

- a special port of the Linux® kernel as the proposed operating system;
- a comprehensive set of tunable DSP algorithms for modems and voice processing, specially tailored to be run by the DSP subsystems;
- a broad range of application level software modules such as H323 telephony or POP-3/SMTP mail services.

Smart Internet Appliance Processor (SIAP™)

Application Example

Figure 2. Standalone Internet Telephone

Functional Description

ARM7TDMI Core

The ARM7TDMI is a three-stage pipeline, 32-bit RISC processor. The processor architecture is Von Neumann load/store architecture which is characterized by a single data and address bus for instructions and data. The CPU has two instruction sets: the ARM and the Thumb instruction set. The ARM instruction set has 32-bit wide instructions and provides maximum performance. Thumb instructions are 16 bits wide and give maximum code density. Instructions operate on 8-, 16- and 32-bit data types.

The CPU has seven operating modes. Each operating mode has dedicated banked registers for fast exception handling. The processor has a total of 37 32-bit registers, including six status registers.

DSP Subsystem

The AT75C310 has two identical DSP subsystems.

Each DSP subsystem is composed of:

- An OakDSPCore running at 40 MIPS
- 2K x 16 of X-RAM
- 2K x 16 of Y-RAM
- 16K x 16 of general purpose data RAM
- 24K x 16 of loadable program RAM
- One 256 x 16 dual-port mailbox
- One codec interface

The DSP subsystem is fully autonomous. The local X- and Y-RAM allow it to reach its maximum processing rate, and a local large data RAM enables complex DSP algorithms to be implemented. The large size of the loadable program RAM permits the use of functions as complex as a V.34 modem or a low bit-rate vocoder.

During boot time, the ARM7TDMI core has the ability to maintain the OakDSPCore in reset state and to upload DSP boot code. When the OakDSPCore reverts to an active state, this boot code can be used to get the complete DSP application code from the ARM7TDMI through the mailbox.

When the OakDSPCore is running the dual-port mailbox is used as the communication channel between the ARM7TDMI and the OakDSPCore.

One programmable codec interface is directly connected to each OakDSPCore. It allows the connection of most industrial voice, multimedia or data codecs.

Boot ROM

The ARM7TDMI has the ability to boot either from an external memory or from the on-chip 256 x 32-bit boot ROM.

Boot Code Operation

The internal boot sequence allows programming of the ARM7TDMI program RAM through a serial port. When the download is complete, a branch is executed to the downloaded code.

EBI: External Bus Interface

The EBI generates the signals that control access to external memory or memory-mapped peripherals. The EBI is fully programmable and can address up to 64M bytes. The interface to external devices is composed of common address and data buses and separate control lines to allow the connection of static or dynamic devices.

The main features are:

- External memory mapping
- Up to two chip select lines
- 8- or 16-bit data bus
- Byte write or byte select lines
- Remap of boot memory
- Support for both static and dynamic memories
- Two different read protocols for static memories
- Support for early read/early write for dynamic memories
- Programmable wait state generation
- Programmable data float time

AIC: Advanced Interrupt Controller

The AT75C310 has an 8-level priority interrupt controller. The interrupt controller outputs are connected to the NFIQ (fast interrupt request) and the NIRQ (normal interrupt request) of the ARM7TDMI core. The processor's NFIQ can only be asserted by the external fast interrupt request input (FIQ). The NIRQ line can be asserted by the interrupts generated by the on-chip peripherals or by the external interrupt request line IRQ0.

An 8-level priority encoder allows the application to define the priority between the different interrupt sources. Interrupt sources are programmed to be level sensitive or edge sensitive. External sources can be programmed to be positive- or negative-edge triggered, or low- or high-level sensitive.

PIO: Parallel I/O Controller

The AT75C310 has 23 programmable I/O lines. They can all be programmed as inputs or outputs. To optimize the use of available package pins, most of them are multiplexed with external signals of on-chip peripherals.

The PIO lines are controlled by two separate and identical PIO controllers called PIOA and PIOB.

The PIO controllers enable the generation of an interrupt on input change and insertion of a simple glitch filter on each PIO line.

Some I/O lines have enough drive capability to power a LED.

USART: Universal Synchronous/ Asynchronous Receiver/ Transmitter

The AT75C310 provides two identical full-duplex, universal synchronous/asynchronous receiver/transmitters that interface to the APB and are connected to the peripheral data controller.

The main features are:

- Programmable baud rate generator
- Parity, framing and overrun error detection
- Line break generation and detection
- Automatic echo, local loopback and remote loopback
- Multi-drop mode: address detection and generation
- Interrupt generation
- Dedicated peripheral data controller channels
- 6-, 7-, 8- and 9-bit character length
- In addition to the Tx and Rx signals, the USART A provides several modem control lines.

SPI: Serial Peripheral Interface

The AT75C310 includes an SPI that provides communication with external devices in master or slave mode.

The SPI has four external chip selects that can be connected to up to 15 devices. The data length is programmable from 8- to 16-bit.

Timer/Counter

The AT75C310 features three identical 16-bit timer/counters. They can be independently programmed to perform a wide range of functions, including frequency measurement, event counting, interval measurement, pulse generation, delay timing and pulse width modulation.

The triple timer/counter block has three external clock inputs, five internal clock inputs and two multi-purpose signals that can be configured by the user. Each timer drives an internal interrupt signal that can be programmed to generate processor interrupts via the advanced interrupt controller.

Watchdog Timer

The AT75C310 has an internal watchdog timer that can be used to prevent system lock-up if the software becomes trapped in a deadlock.

Special Functions

The AT75C310 provides registers that implement the following special functions:

- Chip identification
- Reset status

Application Software

The AT75C310 is supported by a comprehensive range of software modules. As a result of the widespread use of the ARM7TDMI and the OakDSPCore, a wide range is available, either directly from Atmel or from third parties.

The application software modules are in three categories: OS level, DSP level and application level.

OS Level

The AT75C310 is supplied with a customized port of the Linux kernel. It features device drivers for all the on-chip peripherals, including the DSP subsystems, and supports virtual file system usage. It also supports the native TCP/IP facilities that have made Linux a success in Internet applications. This kernel is available in source code under the terms of the Gnu Public License.

Many other operating systems exist for the ARM7TDMI core.

DSP Level

A wide range of DSP functions is available for the OakDSPCore. Among others, Atmel supplies modules for a V.34 modem, G723.1 and G729A voice codecs, silence compression and echo cancellation.

Many third parties also provide ready-to-use libraries for the OakDSPCore.

Application Level

A rich software toolkit is available with support for popular communication protocols (H323, POP-3/SMTP, etc.), connection processes, multimedia applications, full-feature telephony and audio software suites.

Development Tools

Both the ARM7TDMI and the OakDSPCore are industry-standard cores. They are supported by a comprehensive range of state-of-the-art development tools, including assemblers, C-compilers, source level debuggers and hardware emulators.

Packaging

The AT75C310 is supplied in a 160-lead PQFP package. This provides the best compromise between external connectivity and cost.

An alternative 240-lead PQFP package is also available. In addition to a larger I/O capability, it provides the application developer with the possibility of using advanced development tools for the DSP subsystem software.

Although this 240-lead PQFP package is more dedicated to development, it can also be used in production for systems that require a high level of connectivity: it offers up to 48 general-purpose I/Os and a full-width system bus (24 address bits and 32 data bits).

Figure 3. PQFP Package Drawing

For package data, see Table 3, Table 4 and Table 5 below.
