

erate all the required access control signal timing for DRAMs. An on-chip refresh request clock is used to auto-

matically refresh the DRAM array. Refreshes and accesses

are arbitrated on chip. If necessary, a WAIT or DTACK out-

put inserts wait states into system access cycles, including

burst mode accesses. RAS low time during refreshes and

RAS precharge time after refreshes and back to back ac-

cesses are guaranteed through the insertion of wait states.

Separate on-chip precharge counters for each RAS output

can be used for memory interleaving to avoid delayed back

to back accesses because of precharge. An additional fea-

ture of the DP8422A is two access ports to simplify dual

accessing. Arbitration among these ports and refresh is

# **General Description**

done on chip.

**Features** 

- The DP8420A/21A/22A dynamic RAM controllers provide a low cost, single chip interface between dynamic RAM and all 8-, 16- and 32-bit systems. The DP8420A/21A/22A genmicroCMOS process for low power
  - High capacitance drivers for RAS, CAS, WE and DRAM address on chip
  - On chip support for nibble, page and static column DRAMs
  - Byte enable signals on chip allow byte writing in a word size up to 32 bits with no external logic
  - Selection of controller speeds: 20 MHz and 25 MHz
    - On board Port A/Port B (DP8422A only)/refresh arbitration logic
  - Direct interface to all major microprocessors (application notes available)
  - 4 RAS and 4 CAS drivers (the RAS and CAS configuration is programmable)

### 15.0 DP8420A/21A/22A USER HINTS

# **1.0 Introduction**

The DP8420A/21A/22A are CMOS Dynamic RAM controllers that incorporate many advanced features which include address latches, refresh counter, refresh clock, row, column and refresh address multiplexer, delay line, refresh/access arbitration logic and high capacitive drivers. The programmable system interface allows any manufacturer's microprocessor or bus to directly interface via the DP8420A/21A/22A to DRAM arrays up to 64 Mbytes in size.

After power up, the user must first reset and program the DP8420A/21A/22A before accessing the DRAM. The chip is programmed through the address bus.

### Reset:

Due to the differences in power supplies, the internal reset circuit may not always reset correctly; therefore, an External (hardware) Reset must be performed before programming the chip.

### **Programming:**

After resetting the chip, the user can program the controller by either one of two methods: Mode Load Only Programming or Chip Select Access Programming.

### Initialization Period:

Once the DP8420A/21A/22A has been programmed for the first time, a 60 ms initialization period is entered. During this time the DRC performs refreshes to the DRAM array so further warm up cycles are unnecessary. The initialization period is entered only after the first programming after a reset.

### Accessing Modes:

After resetting and programming the chip, the DP8420A/21A/22A is ready to access the DRAM. There are two modes of accessing with these controllers. Mode 0, which indicates  $\overline{\text{RAS}}$  synchronously and Mode 1, which indicates  $\overline{\text{RAS}}$  asynchronously.

### **Refresh Modes:**

The DP8420A/21A/22A have expanded refresh capabilities compared to previous DRAM controllers. There are three modes of refreshing available: Internal Automatic Refreshing, Externally Controlled/Burst Refreshing and Refresh Request/Acknowledge Refreshing. Any of these modes can be used together or separately to achieve the desired results.

### **Refresh Types:**

These controllers have three types of refreshing available: Conventional, Staggered and Error Scrubbing. Any refresh control mode can be used with any type of refresh.

### Wait Support:

The DP8420A/21A/22A have wait support available as DTACK or WAIT. Both are programmable. DTACK, Data Transfer ACKnowledge, is useful for processors whose wait signal is active high. WAIT is useful for those processors whose wait signal is active low. The user can choose either at programming. These signals are used by the on chip arbiter to insert wait states to guarantee the arbitration between accesses, refreshes and precharge. Both signals are independent of the access mode chosen and both signals can be dynamically delayed further through the WAITIN signal to the DP8420A/21A/22A.

### Sequential Accesses (Static Column/Page Mode):

The DP8420A/21A/22A have address latches, used to latch the bank, row and column address inputs. Once the address is latched, a COLumn INCrement (COLINC) feature can be used to increment the column address. The address latches can also be programmed to be fall through. COLINC can be used for Sequential Accesses of Static Column DRAMs. Also, COLINC in conjunction with ECAS inputs can be used for Sequential Accesses to Page Mode DRAMs.

### RAS and CAS Configuration (Byte Writing):

The  $\overrightarrow{RAS}$  and  $\overrightarrow{CAS}$  drivers can be configured to drive a one, two or four bank memory array up to 32 bits in width. The  $\overrightarrow{ECAS}$  signals can then be used to select one of four  $\overrightarrow{CAS}$ drivers for Byte Writing with no extra logic.

### Memory Interleaving:

When configuring the DP820A/21A/22A for more than one bank, Memory Interleaving can be used. By tying the low order address bits to the bank select lines B0 and B1, sequential back to back accesses will not be delayed since these controllers have separate precharge counters per bank.

### Address Pipelining:

The DP8420A/21A/22A are capable of performing Address Pipelining. In address pipelining, the DRC will guarantee the column address hold time and switch the internal multiplexor to place the row address on the address bus. At this time, another memory access to another bank can be initiated.

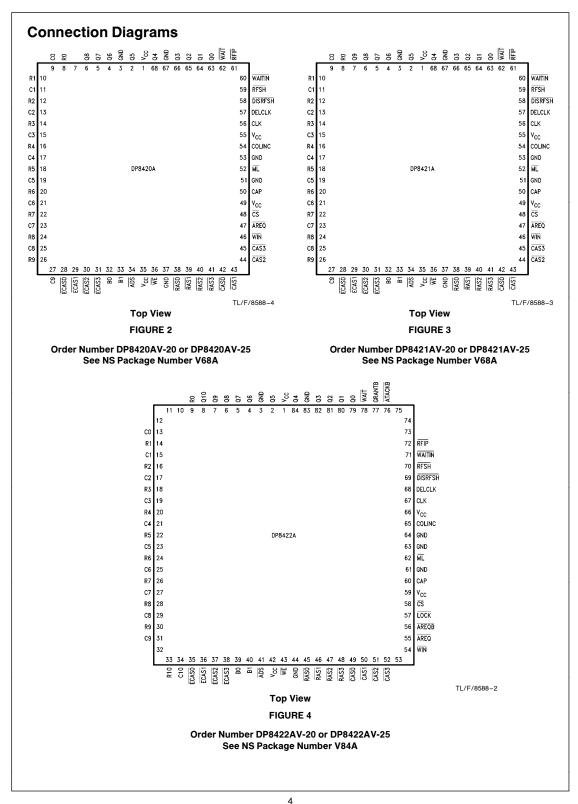

### **Dual Accessing:**

Finally, the DP8422A has all the features previously mentioned and unlike the DP8420A/21A, the DP8422A has a second port to allow a second CPU to access the same memory array. The DP8422A has four signals to support Dual Accessing, these signals are AREOB, ATACKB, LOCK and GRANTB. All arbitration for the two ports and refresh is done on chip by the controller through the insertion of wait states. Since the DP8422A has only one input address bus, the address lines must be multiplexed externally. The signal GRANTB can be used for this purpose.

### Terminology:

The following explains the terminology used in this data sheet. The terms negated and asserted are used. Asserted refers to a "true" signal. Thus, "ECAS0 asserted" means the ECAS0 input is at a logic 0. The term "COLINC asserted" means the COLINC input is at a logic 1. The term negated refers to a "false" signal. Thus, "ECAS0 negated" means the ECAS0 input is at a logic 1. The term "COLINC negated" means the input COLINC is at a logic 0. The table shown below clarifies this terminology.

Signal	Action	Logic Level
Active High	Asserted	High
Active High	Negated	Low
Active Low	Asserted	Low
Active Low	Negated	High

Pin Name	Device (If not Applicable to All)	Input/ Output	Description
2.1 ADDRESS	, R/W AND PROGRA	AMMING	SIGNALS
R0-10 R0-9	DP8422A DP8420A/21A	l	<b>ROW ADDRESS:</b> These inputs are used to specify the row address during an access to the DRAM. They are also used to program the chip when ML is asserted (except R10).
C0-10 C0-9	DP8422A DP8420A/21A	I	<b>COLUMN ADDRESS:</b> These inputs are used to specify the column address during an access to the DRAM. They are also used to program the chip when $\overline{\text{ML}}$ is asserted (except C10).
B0, B1		Ι	<b>BANK SELECT:</b> Depending on programming, these inputs are used to select a group of $\overrightarrow{RAS}$ and $\overrightarrow{CAS}$ outputs to assert during an access. They are also used to program the chip when $\overrightarrow{ML}$ is asserted.
ECAS0-3		Ι	<b>ENABLE CAS:</b> These inputs are used to enable a single or group of CAS outputs when asserted. In combination with the B0, B1 and the programming bits, these inputs select which CAS output or CAS outputs will assert during an access. The ECAS signals can also be used to toggle a group of CAS outputs for page/hibble mode accesses. They also can be used for byte write operations. If ECAS0 is negated during programming, continuing to assert the ECAS0 while negating AREQ or AREQB during an access, will cause the CAS0 outputs to be extended while the RAS outputs are negated (the ECASn inputs have no effect during scrubbing refreshes).
WIN		Ι	<b>WRITE ENABLE IN:</b> This input is used to signify a write operation to the DRAM. If ECAS0 is asserted during programming, the $\overline{WE}$ output will follow this input. This input asserted will also cause $\overline{CAS}$ to delay to the next positive clock edge if address bit C9 is asserted during programming.
COLINC (EXTNDRF)		l	<b>COLUMN INCREMENT:</b> When the address latches are used, and $\overline{\text{RFIP}}$ is negated, this input functions as COLINC. Asserting this signal causes the column address to be incremented by one. When $\overline{\text{RFIP}}$ is asserted, this signal is used to extend the refresh cycle by any number of periods of CLK until it is negated.
ML		Ι	<b>MODE LOAD:</b> This input signal, when low, enables the internal programming register that stores the programming information.
2.2 DRAM CO	NTROL SIGNALS		
Q0-10 Q0-9 Q0-8	DP8422A DP8421A DP8421A	0 0 0	<b>DRAM ADDRESS:</b> These outputs are the multiplexed output of the R0–9, 10 and C0–9, 10 and form the DRAM address bus. These outputs contain the refresh address whenever $\overrightarrow{RFIP}$ is asserted. They contain high capacitive drivers with 20 $\Omega$ series damping resistors.
RAS0-3		0	<b>ROW ADDRESS STROBES:</b> These outputs are asserted to latch the row address contained on the outputs $Q0-8$ , 9, 10 into the DRAM. When RFIP is asserted, the RAS outputs are used to latch the refresh row address contained on the $Q0-8$ , 9, 10 outputs in the DRAM. These outputs contain high capacitive drivers with $20\Omega$ series damping resistors.
CAS0-3		0	<b>COLUMN ADDRESS STROBES:</b> These outputs are asserted to latch the column address contained on the outputs $Q0-8$ , 9, 10 into the DRAM. These outputs have high capacitive drivers with $20\Omega$ series damping resistors.
WE (RFRQ)		0 0	<b>WRITE ENABLE</b> or <b>REFRESH REQUEST:</b> This output asserted specifies a write operation to the DRAM. When negated, this output specifies a read operation to the DRAM. When the DP8420A/21A/22A is programmed in address pipelining mode or when ECAS0 is negated during programming, this output will function as RFRQ. When asserted, this pin specifies that 13 $\mu$ s or 15 $\mu$ s have passed. If DISRFSH is negated, the DP8420A/21A/22A will perform an internal refresh as soon as possible. If DISRFRSH is asserted, RFRQ can be used to externally request a refresh through the input RFSH. This output has a high capacitive driver and a 20 $\Omega$ series damping resistor.

Pin Name	Device (If not Applicable to All)	Input/ Output	Description		
2.5 PORT B	ACCESS SIGNALS				
AREQB	DP8422A only	I	<b>PORT B ACCESS REQUEST:</b> This input asserted will latch the row, column and ban address if programmed, and requests an access to take place for Port B. If the access can take place, RAS will assert immediately. If the access has to be delayed, RAS will assert as soon as possible from a positive edge of CLK.		
ATACKB	DP8422A only	0	ADVANCED TRANSFER ACKNOWLEDGE PORT B: This output is asserted when the access $\overrightarrow{RAS}$ is asserted for a Port B access. This signal can be used to generate the appropriate $\overrightarrow{DTACK}$ or $\overrightarrow{WAIT}$ type signal for Port B's CPU or bus.		
2.6 COMMO	N DUAL PORT SIGN	ALS			
GRANTB	DP8422A only	0	<b>GRANT B:</b> This output indicates which port is currently granted access to the DRAM array. When GRANTB is asserted, Port B has access to the array. When GRANTB is negated, Port A has access to the DRAM array. This signal is used to multiplex the signals R0–8, 9, 10; C0–8, 9, 10; B0–1; WIN; LOCK and ECAS0–3 to the DP8422A when using dual accessing.		
LOCK	DP8422A only	I	<b>LOCK:</b> This input can be used by the currently granted port to "lock out" the other port from the DRAM array by inserting wait states into the locked out port's access cycle until LOCK is negated.

# 3.0 Programming and Resetting

Due to the variety in power supplies power-up times, the internal power up reset circuit may not work in every design; therefore, an EXTERNAL RESET must be performed before the DRAM controller can be programmed and used.

After going through the reset procedure, the DP8420A/21A/22A can be programmed by either of two methods; Mode Load Only Programming or Chip Select Access Programming. After programming the DRC for the first time after reset, the chip enters a 60 ms initialization period, during this period the controller performs refreshes every 13  $\mu$ s or 15  $\mu$ s, this makes further DRAM warm up cycles unnecessary. After this stage the chip can be reprogrammed as many times as the user wishes and the 60 ms period will not be entered into unless the chip is reset and programmed again.

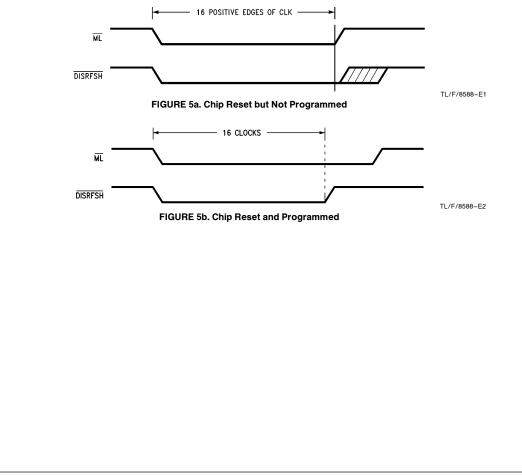

During the 60 ms initialization period,  $\overline{\text{RFIP}}$  is asserted low and  $\overline{\text{RAS}}$  toggles every 13  $\mu$ s or 15  $\mu$ s depending on the programming bit for refresh (C3).  $\overline{\text{CAS}}$  will be inactive (logic 1) and the "Q" outputs will count from 0 to 2047 refreshing the entire DRAM array. The actual initialization time period is given by the following formula. T = 4096\* (Clock Divisor Select)\* (Refresh Clock Fine Tune)/(DELCLK Frq.)

### 3.1 EXTERNAL RESET

At power up, if the internal power up reset worked, all internal latches and flip-flops are cleared and the part is ready to be programmed. The power up state can also be achieved by performing an External Reset, which is required to insure proper operation. External Reset is achieved by asserting  $\overline{\text{ML}}$  and  $\overline{\text{DISRFSH}}$  for at least 16 positive clock edges. In order to perform simply a Reset, the  $\overline{\text{ML}}$  signal must be negated before  $\overline{\text{DISRFSH}}$  is negated as shown in *Figure 5a*. This procedure will only reset the controller which now is ready for programming.

While performing an External Reset, if the user negates DISRFSH at least one clock period before negating  $\overline{ML}$ , as shown in *Figure 5b*,  $\overline{ML}$  negated will program the DP8420A/21A/22A with the values in R0–9, C0–9, B0–1 and ECAS0. The 60 ms initialization period will be entered since it is the first programming after reset. This is a good way of resetting and programming the part at the same time. Make sure the right programming bits are on the address lines before  $\overline{ML}$  is negated.

The DRC may be Reset and programmed any time on the fly, but the user must make sure that No Access or Refresh is in progress.

# 3.0 Programming and Resetting (Continued)

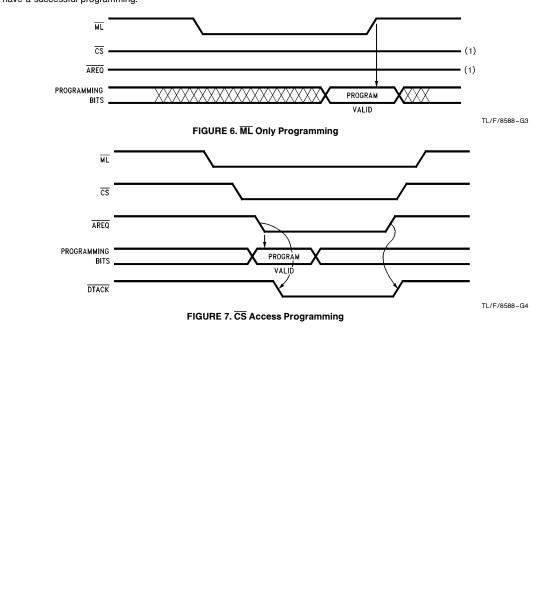

# 3.2 PROGRAMMING METHODS

# 3.2.1 Mode Load Only Programming

To use this method the user asserts  $\overline{\text{ML}}$  enabling the internal programming register. After  $\overline{\text{ML}}$  is asserted, a valid programming selection is placed on the address bus, B0, B1 and  $\overline{\text{ECAS0}}$  inputs, then  $\overline{\text{ML}}$  is negated. When  $\overline{\text{ML}}$  is negated the programming bits are latched into the internal programming register and the DP8420A/21A/22A is programmed, see *Figure 6*. When programming the chip, the controller must not be refreshing, RFIP must be high (1) to have a successful programming.

### 3.2.2 Chip Selected Access Programming

The chip can also be programmed by performing a chip selected access. To program the chip using this method,  $\overline{\text{ML}}$  is asserted, then  $\overline{\text{CS}}$  is asserted and a valid programming selection is placed on the address bus. When  $\overline{\text{AREQ}}$  is asserted, the programming bits affecting the wait logic become effective immediately, then  $\overline{\text{DTACK}}$  is asserted allowing the access to terminate. After the access,  $\overline{\text{ML}}$  is negated and the rest of the programming bits take effect.

Symbol	Description					
ECAS0	Extend CAS/Refresh Request Select					
0	The $\overline{CASn}$ outputs will be negated with the $\overline{RASn}$ outputs when $\overline{AREQ}$ (or $\overline{AREQB}$ , DP8422A only) is negated. The $\overline{WE}$ output pin will function as write enable.					
1	The CASn outputs will be negated, during an acccess (Port A (or Port B, DP8422A only)) when their corresponding ECASn inputs are negated. This feature allows the CAS outputs to be extended beyond the outputs negating. Scrubbing refreshes are NOT affected. During scrubbing refreshes the CAS outputs will n along with the RAS outputs regardless of the state of the ECAS inputs. The WE output will function as ReFresh ReQuest (RFRQ) when this mode is programmed.					
B1	Access Mode Select					
0	ACCESS MODE 0: ALE pulsing high sets an internal latch. On the next positive edge of CLK, the access (RAS) will start. AREQ will terminate the access.					
B0	ACCESS MODE 1: ADS asserted starts the access (RAS) immediately. AREQ will terminate the access. Address Latch Mode					
0	Address Laten mode ADS or ALE asserted for Port A or AREQB asserted for Port B with the appropriate GRANT latch the input row, column and bank address.					
1	The row, column and bank latches are fall through.					
C9	Delay CAS during WRITE Accesses					
0 1	CAS is treated the same for both READ and WRITE accesses. During WRITE accesses, CAS will be asserted by the event that occurs last: CAS asserted by the internal delay line or CAS asserted on the positive edge of CLK after RAS is asserted.					
C8	Row Address Hold Time					
0	Row Address Hold Time = 25 ns minimum					
1	Row Address Hold Time = 15 ns minimum					
C7	Column Address Setup Time					
0	Column Address Setup Time = 10 ns miniumum					
1	Column Address Setup Time = 0 ns minimum					
C6, C5, C4	RAS and CAS Configuration Modes/Error Scrubbing during Refresh					
0, 0, 0	RAS0-3 and CAS0-3 are all selected during an access. ECASn must be asserted for CASn to be asserted.         B0 and B1 are not used during an access. Error scrubbing during refresh.					
0, 0, 1	<ul> <li>RAS and CAS pairs are selected during an access by B1. 1, 1, 1	$\overline{RAS}$ and $\overline{CAS}$ singles are selected by B0, 1. $\overline{ECAS}$ n must be asserted for $\overline{CAS}$ n to be asserted.
., ., .	B1 = 0, B0 = 0 during an access selects $\overline{RAS}0$ and $\overline{CAS}0$ .
	B1 = 0, B0 = 1 during an access selects $\overline{RAS}$ 1 and $\overline{CAS}$ 1.
	B1 = 1, B0 = 0 during an access selects $\overline{RAS2}$ and $\overline{CAS2}$ .
	B1 = 1, B0 = 1 during an access selects RAS3 and CAS3. No error scrubbing.
C3	Refresh Clock Fine Tune Divisor
0	Divide delay line/refresh clock further by 30 (If DELCLK/Refresh Clock Clock Divisor = 2 MHz = 15 $\mu$ s
1	refresh period). Divide delay line/refresh clock further by 26 (If DELCLK/Refresh Clock Clock Divisor = 2 MHz = 13 $\mu$ s
1	refresh period).
C2, C1, C0	Delay Line/Refresh Clock Divisor Select
0, 0, 0	Divide DELCLK by 10 to get as close to 2 MHz as possible.
0, 0, 1	Divide DELCLK by 9 to get as close to 2 MHz as possible.
0, 1, 0 0, 1, 1	Divide DELCLK by 8 to get as close to 2 MHz as possible. Divide DELCLK by 7 to get as close to 2 MHz as possible.
1, 0, 0	Divide DELCLK by 6 to get as close to 2 MHz as possible.
1, 0, 1	Divide DELCLK by 5 to get as close to 2 MHz as possible.
1, 1, 0	Divide DELCLK by 4 to get as close to 2 MHz as possible.
1, 1, 1	Divide DELCLK by 3 to get as close to 2 MHz as possible.
R9	Refresh Mode Select
0	RAS0-3 will all assert and negate at the same time during a refresh. Staggered Refresh. RAS outputs during refresh are separated by one positive clock edge. Depending on the
1	configuration mode chosen, either one or two RASs will be asserted.
R8	Address Pipelining Select
0	Address pipelining is selected. The DRAM controller will switch the DRAM column address back to the row
	address after guaranteeing the column address hold time.
1	Non-address pipelining is selected. The DRAM controller will hold the column address on the DRAM address bus until the access RASs are negated.
R7	WAIT or DTACK Select
0	WAIT type output is selected.
1	DTACK (Data Transfer ACKnowledge) type output is selected.
R6	Add Wait States to the Current Access if WAITIN is Low
0	WAIT or DTACK will be delayed by one additional positive edge of CLK.
1	WAIT or DTACK will be delayed by two additional positive edges of CLK.

	Description					
R5, R4	WAIT/DTACK during Burst (See Section 5.1.2 or 5.2.2)					
0, 0	NO WAIT STATES; If $R7 = 0$ during programming, WAIT will remain negated during burst portion of access. If $R7 = 1$ programming, DTACK will remain asserted during burst portion of access.					
0, 1	1T; If $R7 = 0$ during programming, WAIT will assert when the ECAS inputs are negated with $\overline{AREQ}$ asserted. WAIT will negate from the positive edge of CLK after the ECASs have been asserted. If $R7 = 1$ during programming, DTACK will negate when the ECAS inputs are negated with $\overline{AREQ}$ asserted. DTACK will assert from the positive edge of CLK after the ECASs have been asserted.					
1, 0	$\frac{1}{2}$ T; If R7 = 0 during programming, WAIT will assert when the ECAS inputs are negated with $\overline{AREQ}$ ass WAIT will negate on the negative level of CLK after the ECASs have been asserted. If R7 = 1 during programming, DTACK will negate when the ECAS inputs are negated with $\overline{AREQ}$ asser DTACK will assert from the negative level of CLK after the ECASs have been asserted.					
1, 1	OT; If R7 = 0 during programming, WAIT will assert when the ECAS inputs are negated. WAIT will negate when the ECAS inputs are asserted. If R7 = 1 during programming, DTACK will negate when the ECAS inputs are negated. DTACK will assert when the ECAS inputs are asserted.					
R3, R2	WAIT/DTACK Delay Times (See Section 5.1.1 or 5.2.1)					
0, 0	NO WAIT STATES; If $R7 = 0$ during programming, WAIT will remain high during non-delayed accesses. WAIT will negate when RAS is negated during delayed accesses. NO WAIT STATES; If $R7 = 1$ during programming, DTACK will be asserted when RAS is asserted.					
0, 1	$\frac{1}{2}$ T; If R7 = 0 during programming, WAIT will negate on the negative level of CLK, after the access RAS. 1T; If R7 = 1 during programming, DTACK will be asserted on the positive edge of CLK after the access RAS.					
1, 0	NO WAIT STATES, $\frac{1}{2}$ T; If R7 = 0 during programming, WAIT will remain high during non-delayed accesses. WAIT will negate on the negative level of CLK, after the access RAS, during delayed accesses. $\frac{1}{2}$ T; If R7 = 1 during programming, DTACK will be asserted on the negative level of CLK after the access RAS.					
1, 1	1T; If $R7 = 0$ during programming, WAIT will negate on the positive edge of CLK after the access RAS. 1½T; If $R7 = 1$ during programming, DTACK will be asserted on the negative level of CLK after the positive edg of CLK after the access RAS.					
R1, R0	RAS Low and RAS Precharge Time					
0, 0	$\overline{\text{RAS}}$ asserted during refresh = 2 positive edges of CLK. $\overline{\text{RAS}}$ precharge time = 1 positive edge of CLK. $\overline{\text{RAS}}$ will start from the first positive edge of CLK after GRANTB transitions (DP8422A).					
0, 1	$\overrightarrow{\text{RAS}}$ asserted during refresh = 3 positive edges of CLK. $\overrightarrow{\text{RAS}}$ precharge time = 2 positive edges of CLK. $\overrightarrow{\text{RAS}}$ will start from the second positive edge of CLK after GRANTB transitions (DP8422A).					
1, 0	$\overline{\text{RAS}}$ asserted during refresh = 2 positive edges of CLK. $\overline{\text{RAS}}$ precharge time = 2 positive edges of CLK. $\overline{\text{RAS}}$ will start from the first positive edge of CLK after GRANTB transitions (DP8422A).					
1, 1	$\overline{\text{RAS}}$ asserted during refresh = 4 positive edges of CLK. $\overline{\text{RAS}}$ precharge time = 3 positive edges of CLK. $\overline{\text{RAS}}$ will start from the second positive edge of CLK after GRANTB transitions (DP8422A).					

# 4.0 Port A Access Modes

The DP8420A/21A/22A have two general purpose access modes. Mode 0 RAS synchronous and Mode 1 RAS asynchronous. One of these modes is selected at programming through the B1 input. A Port A access to DRAM is initiated by two input signals:  $\overline{\text{ADS}}$  (ALE) and  $\overline{\text{CS}}$ . The access is always terminated by one signal:  $\overline{\text{AREQ}}$ . These input signals should be synchronous to the input clock.

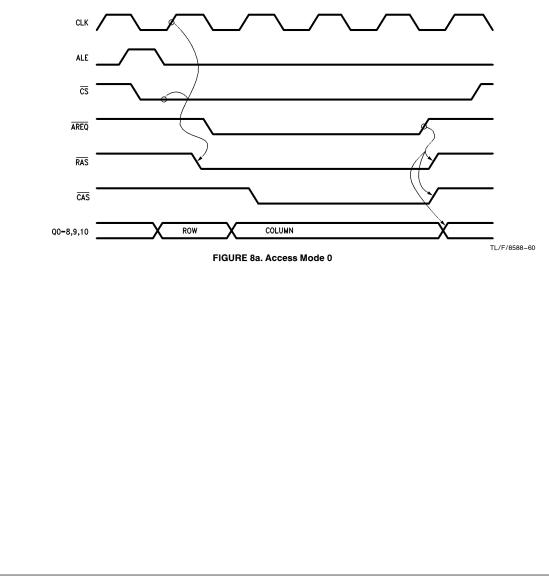

### 4.1 ACCESS MODE 0

Mode 0, synchronous access, is selected by negating the input B1 during programming (B1=0). To initiate a Mode 0 access, ALE is pulse high and  $\overline{\text{CS}}$  is asserted. If precharge time was met, a refresh of DRAM or a Port B access was not in progress, the  $\overline{\text{RAS}}$  ( $\overline{\text{RASs}}$ ) would be asserted on the

first rising edge of clock. If a refresh or a Port B access is in progress or precharge time is required, the controller will wait until these events have taken place and assert  $\overline{RAS}$  ( $\overline{RAS}$ s) on the next positive edge of clock.

Sometime after the first positive edge of clock after ALE and  $\overline{CS}$  have been asserted, the input  $\overline{AREQ}$  must be asserted. In single port applications, once  $\overline{AREQ}$  is asserted,  $\overline{CS}$  can be negated. On the other hand, ALE can stay asserted several periods of clock; however, ALE must be negated before or during the period of CLK in which  $\overline{AREQ}$  is negated.

The controller samples  $\overline{\text{AREQ}}$  on the every rising edge of clock after  $\overline{\text{DTACK}}$  is asserted. The access will end when  $\overline{\text{AREQ}}$  is sampled negated.

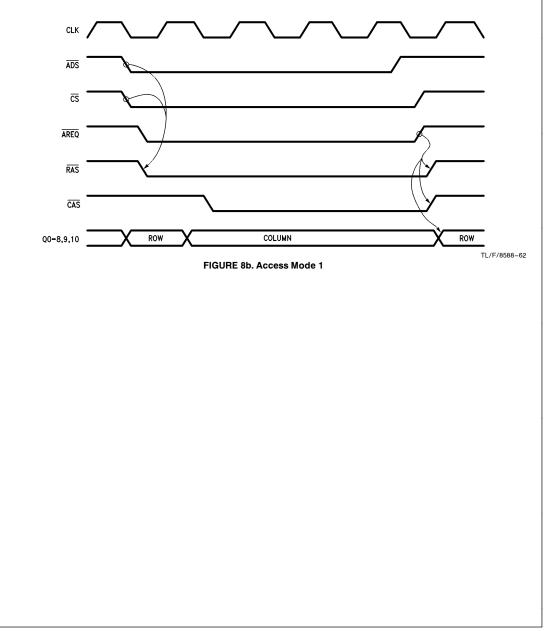

# 4.2 ACCESS MODE 1

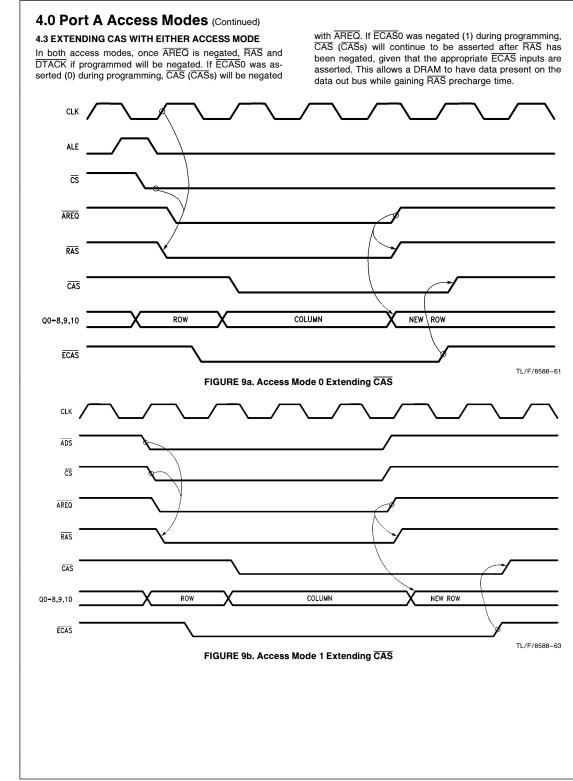

Mode 1, asynchronous access, is selected by asserting the input B1 during programming (B1=1). This mode allows accesses to start immediately from the access request input,  $\overline{\text{ADS}}$ . To initiate a Mode 1 access,  $\overline{\text{CS}}$  is asserted followed by  $\overline{\text{ADS}}$  asserted. If precharge time was met, a refresh of the DRAM or a Port B access was not in progress, the  $\overline{\text{RAS}}$  ( $\overline{\text{RAS}}$ ) would be asserted from  $\overline{\text{ADS}}$  being asserted. If a referse of referse or Port B access is in progress or precharge time is required, the controller will wait until these events have tak-

en place and assert  $\overline{\text{RAS}}$  ( $\overline{\text{RASs}}$ ) from the next rising edge of clock.

When  $\overline{\text{ADS}}$  is asserted or sometime after,  $\overline{\text{AREQ}}$  must be asserted. At this time,  $\overline{\text{ADS}}$  can be negated and  $\overline{\text{AREQ}}$  will continue the access. Also,  $\overline{\text{ADS}}$  can continue to be asserted after  $\overline{\text{AREQ}}$  has been asserted and negated; however, a new access will not start until  $\overline{\text{ADS}}$  is negated and asserted again. When address pipelining is not implemented,  $\overline{\text{ADS}}$  and  $\overline{\text{AREQ}}$  can be tied together.

The access will end when AREQ is negated.

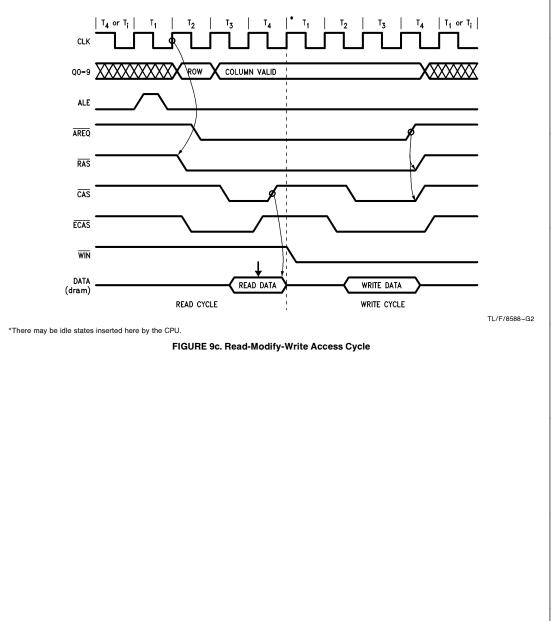

# 4.4 READ-MODIFY-WRITE CYCLES WITH EITHER ACCESS MODE

There are 2 methods by which this chip can be used to do read-modify-write access cycles. The first method involves doing a late write access where the WIN input is asserted some delay after  $\overline{\text{CAS}}$  is asserted. The second method involves doing a page mode read access followed by a page mode write access with  $\overline{\text{RAS}}$  held low (see *Figure 9c*).

 $\overline{\text{CAS}}$ n must be toggled using the  $\overline{\text{ECAS}}$ n inputs and  $\overline{\text{WIN}}$  has to be changed from negated to asserted (read to write) while  $\overline{\text{CAS}}$  is negated. This method is better than changing

WIN from negated to asserted in a late write access because here a problem may arise with DATA IN and DATA OUT being valid at the same time. This may result in a data line trying to drive two different levels simultaneously. The page mode method of a read-modify-write access allows the user to have transceivers in the system because the data in (read data) is guaranteed to be high impedance during the time the data out (write data) is valid.

### 4.5 ADDITIONAL ACCESS SUPPORT FEATURES

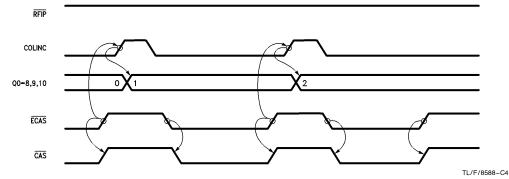

To support the different modes of accessing, the DP8420A/21A/22A offer other access features. These additional features include: Address Latches and Column Increment (for page/burst mode support), Address Pipelining, and Delay  $\overline{CAS}$  (to allow the user with a multiplexed bus to ensure valid data is present before  $\overline{CAS}$  is asserted).

### 4.5.1 Address Latches and Column Increment

The Address Latches can be programmed, through programming bit B0. They can be programmed to either latch the address or remain in a fall-through mode. If the address latches are used to latch the address, the controller will function as follows:

In Mode 0, the rising edge of ALE places the latches in fallthrough, once ALE is negated, the address present in the row, column and bank input is latched. In Mode 1, the address latches are in fall through mode until  $\overline{\text{ADS}}$  is asserted.  $\overline{\text{ADS}}$  asserted latches the address.

Once the address is latched, the column address can be incremented with the input COLINC. COLINC can be used for sequential accesses of static column DRAMs. COLINC can also be used with the ECAS inputs to support sequential accesses to page mode DRAMs as shown in *Figure 10*. COLINC should only be asserted when the signal RFIP is negated during an access since this input functions as extended refresh when RFIP is asserted. COLINC must be negated (0) when the address is being latched (ADS falling edg in Model 1). If COLINC is asserted with all of the bits of the column address asserted (ones), the column address will return to zero.

### FIGURE 10. Column Increment

The address latches function differently with the DP8422A. The DP8422A will latch the address of the currently granted port. If Port A is currently granted, the address will be latched as described in Section 4.5.1. If Port A is not granted, and requests an access, the address will be latched on the first or second positive edge of CLK after GRANTB has been negated depending on the programming bits R0, R1. For Port B, if GRANTB is asserted, the address will be latched with  $\overline{\text{AREQB}}$  asserted. If GRANTB is negated, the address will latch on the first or second positive edge of CLK after GRANTB is asserted depending on the programming bits R0, R1.

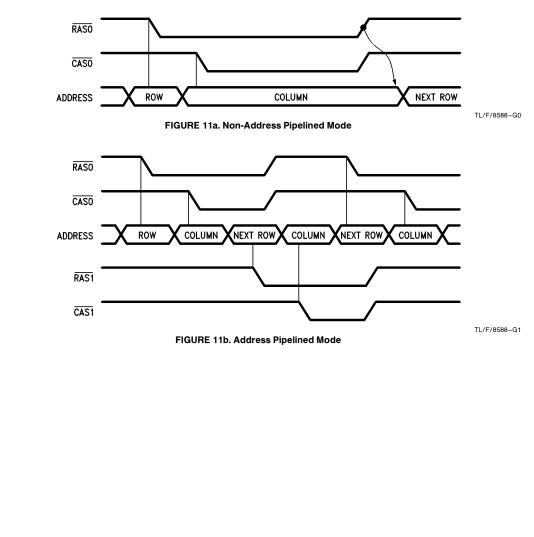

### 4.5.2 Address Pipelining

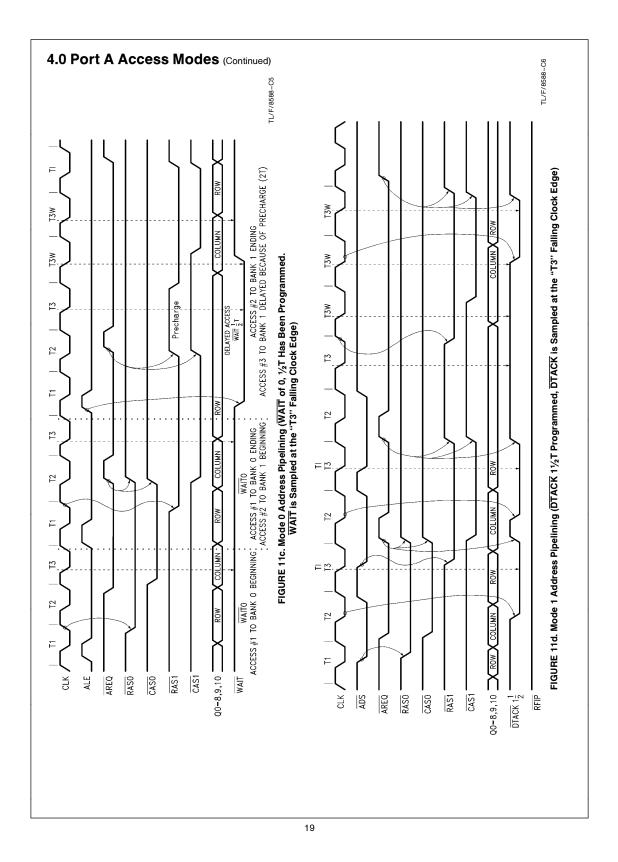

Address pipelining is the overlapping of accesses to different banks of DRAM. If the majority of successive accesses are to a different bank, the accesses can be overlapped. Because of this overlapping, the cycle time of the DRAM accesses are greatly reduced. The DP8420A/21A/22A can be programmed to allow a new row address to be placed on the DRAM address bus after the column address hold time has been met. At this time, a new access can be initiated with ADS or ALE, depending on the access mode, while AREQ is used to sustain the current access. The DP8422A supports address pipelining for Port A only. This mode cannot be used with page, static column or nibble modes of operations because the DRAM column address is switched back to the row address after  $\overline{\text{CAS}}$  is asserted. This mode is programmed through address bit R8 (see Figures 11a and 11b). In this mode, the output  $\overline{\text{WE}}$  always functions as RFRQ.

During address pipelining in Mode 0, shown in *Figure 11c*, ALE cannot be pulsed high to start another access until  $\overline{AREQ}$  has been asserted for the previous access for at least one period of CLK.  $\overline{DTACK}$ , if programmed, will be negated once  $\overline{AREQ}$  is negated. WAIT, if programmed to insert wait states, will be asserted once ALE and  $\overline{CS}$  are asserted.

In Mode 1, shown in *Figure 11d*,  $\overline{\text{ADS}}$  can be negated once  $\overline{\text{AREQ}}$  is asserted. After meeting the minimum negated pulse width for  $\overline{\text{ADS}}$ ,  $\overline{\text{ADS}}$  can again be asserted to start a new access.  $\overline{\text{DTACK}}$ , if programmed, will be negated once  $\overline{\text{AREQ}}$  is negated. WAIT, if programmed, will be asserted once  $\overline{\text{ADS}}$  is asserted.

In either mode with either type of wait programmed, the DP8420A/21A/22A will still delay the access for precharge if sequential accesses are to the same bank or if a refresh takes place.

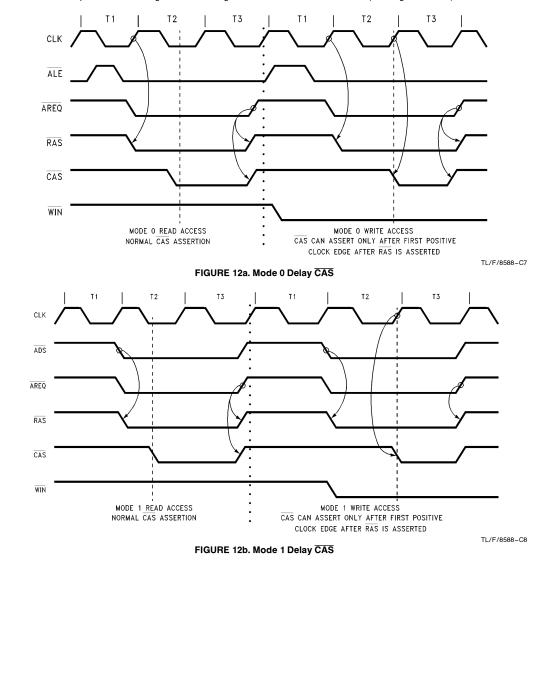

# 4.5.3 Delay CAS during Write Accesses

Address bit C9 asserted during programming will cause  $\overline{CAS}$  to be delayed until the first positive edge of CLK after  $\overline{RAS}$  is asserted when the input  $\overline{WIN}$  is asserted. Delaying  $\overline{CAS}$  during write accesses ensures that the data to be written to DRAM will be setup to  $\overline{CAS}$  asserting as shown in *Figures* 

*12a* and *12b*. If the possibility exists that data still may not be present after the first positive edge of CLK,  $\overline{CAS}$  can be delayed further with the  $\overline{ECAS}$  inputs. If address bit C9 is negated during programming, read and write accesses will be treated the same (with regard to  $\overline{CAS}$ ).

# **5.0 Refresh Options**

The DP8420A/21A/22A support three refresh control mode options:

1. Automatic Internally Controlled Refresh.

2. Externally Controlled/Burst Refresh.

3. Refresh Request/Acknowledge.

With each of the control modes above, three types of refresh can be performed.

- 1. All RAS Refresh.
- 2. Staggered Refresh.

3. Error Scrubbing During All  $\overline{\text{RAS}}$  Refresh.

There are three inputs, EXTNDRF,  $\overline{\text{RFSH}}$  and  $\overline{\text{DISRFSH}}$ , and two outputs,  $\overline{\text{RFIP}}$  and  $\overline{\text{RFRQ}}$ , associated with refresh. There are also ten programming bits: R0–1, R9, C0–6 and ECAS0 used to program the various types of refreshing.

Asserting the input EXTNDRF, extends the refresh cycle for a single or multiple integral periods of CLK.

The output  $\overline{\text{RFIP}}$  is asserted one period of CLK before the first refresh  $\overline{\text{RAS}}$  is asserted. If an access is currently in progress,  $\overline{\text{RFIP}}$  will be asserted up to one period of CLK before the first refresh  $\overline{\text{RAS}}$ , after  $\overline{\text{AREQ}}$  or  $\overline{\text{AREQB}}$  is negated for the access (see *Figure 13*).

The DP8420A/21A/22A will increment the refresh address counter automatically, independent of the refresh mode used. The refresh address counter will be incremented once all the refresh  $\overline{\text{RASs}}$  have been negated.

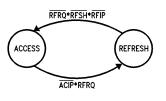

In every combination of refresh control mode and refresh type, the DP8420A/21A/22A is programmed to keep  $\overline{\text{RAS}}$  asserted a number of CLK periods. The time values of  $\overline{\text{RAS}}$  low during refresh are programmed through programming bits R0 and R1.

### 5.1 REFRESH CONTROL MODES

### 5.1.1. Automatic Internal Refresh

The DP8420A/21A/22A have an internal refresh clock. The period of the refresh clock is generated from the programming bits C0–3. Every period of the refresh clock, an internal refresh request is generated. As long as a DRAM access is not currently in progress and precharge time has been met, the internal refresh request will generate an automatic internal refresh. If a DRAM access is in progress, the DP8420A/21A/22A on-chip arbitration logic will wait until the access arbitration logic can insert a refresh. The refresh/access arbitration logic can insert a refresh cycle between two address pipelined accesses. However, the refresh arbitration logic can not interrupt an access cycle to perform a refresh. To enable automatic internally controlled refreshes, the input DISRFSH must be negated.

TI /F/8588-F8

Explanation of Terms

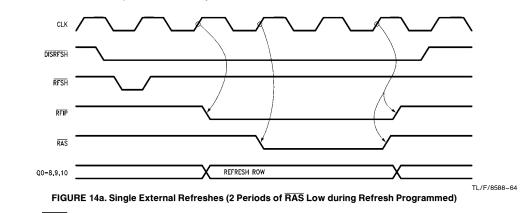

- RFRQ = ReFresh ReQuest internal to the DP8420A/21A/22A. RFRQ has the ability to hold off a pending access.
- RFSH = Externally requested ReFreSH
- RFIP = ReFresh in Progress
- ACIP = Port A or Port B (DP8422A only) ACcess in Progress. This means that either RAS is low for an access or is in the process of transitioning low for an access.

### FIGURE 13. DP8420A/21A/22A Access/Refresh Arbitration State Program

# 5.1.2 Externally Controlled/Burst Refresh

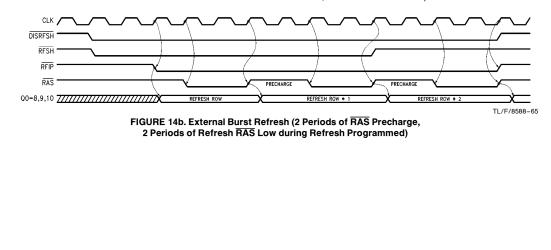

To use externally controlled/burst refresh, the user must disable the automatic internally controlled refreshes by asserting the input  $\overline{\text{DISRFSH}}$ . The user is responsible for generating the refresh request by asserting the input  $\overline{\text{RFSH}}$ . Pulsing  $\overline{\text{RFSH}}$  low, sets an internal latch, that is used to produce the internal refresh request. The refresh cycle will

take place on the next positive edge of CLK as shown in *Figure 14a.* If an access to DRAM is in progress or precharge time for the last access has not been met, the refresh will be delayed. Since pulsing RFSH low sets a latch, the user does not have to keep RFSH low until the refresh starts. When the last refresh RAS negates, the internal refresh request latch is cleared.

By keeping  $\overline{\text{RFSH}}$  asserted past the positive edge of CLK which ends the refresh cycle as shown in *Figure 14b*, the user will perform another refresh cycle. Using this technique, the user can perform a burst refresh consisting of any number of refresh cycles. Each refresh cycle during a burst refresh will meet the refresh  $\overline{\text{RAS}}$  low time and the  $\overline{\text{RAS}}$  precharge time (programming bits R0–1).

If the user desires to burst refresh the entire DRAM (all row addresses) he could generate an end of count signal (burst refresh finished) by looking at one of the DP8420A/21A/22A high address outputs (Q7, Q8, Q9 or Q10) and the  $\overline{\text{RFIP}}$  output. The Qn outputs function as a decode of how many row addresses have been refreshed (Q7 = 128 refreshes, Q8 = 256 refreshes, Q9 = 512 refreshes, Q10 = 1024 refreshes).

### 5.1.3 Refresh Request/Acknowledge

The DP8420A/21A/22A can be programmed to output internal refresh requests. When the user programs  $\overline{ECASO}$  negated (1) and/or address pipelining mode is selected, the  $\overline{WE}$  output functions as  $\overline{RFRQ}$ .  $\overline{RFRQ}$  ( $\overline{WE}$ ) will be asserted by one of two events:

First, when the external circuitry pulses low the input  $\overline{\text{RFSH}}$  which will request an external refresh.

Second, when the internal refresh clock has expired, which signals that another refresh is needed.

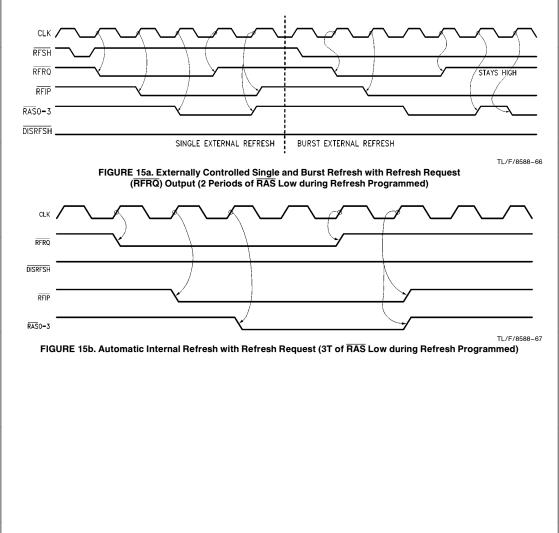

An example of the first case, where an external refresh is requested while  $\overline{\text{RFRQ}}$  is negated (1), is shown in *Figure 15a*. Notice that  $\overline{\text{RFRQ}}$  will be asserted from a positive edge of clock.

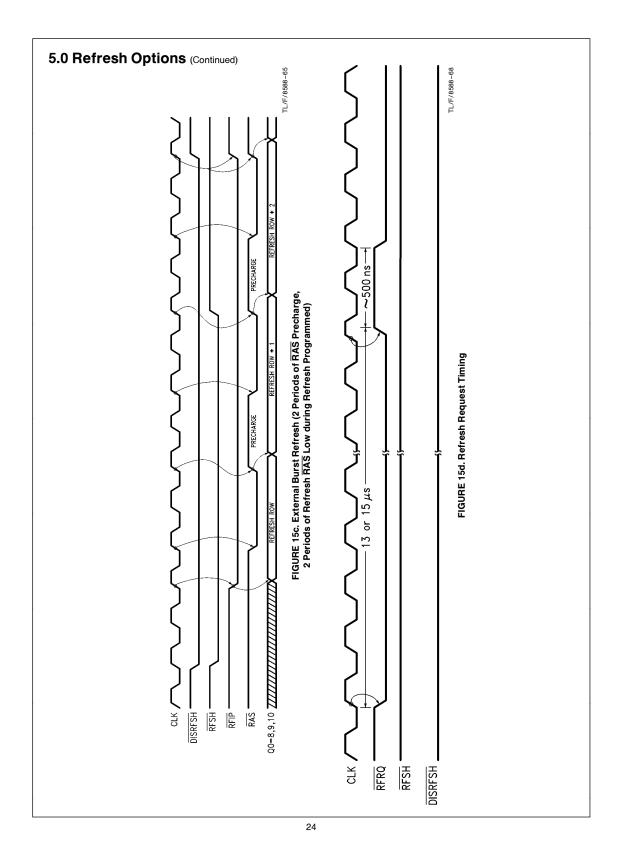

On the second case, when the  $\overline{\text{RFRQ}}$  is asserted from the expiration of the internal refresh clock, the user has two options:

First, if DISRFSH is negated, an automatic internal refresh will take place. See *Figure 15b*.

Second, with DISRFSH asserted, RFRQ will stay asserted until RFSH is pulsed low. This option will cause an externally requested/burst refresh to take place. See *Figure 15c*.

RFRQ will go high and then assert (toggle) if additional periods of the internal refresh clock have expired and neither an externally controlled refresh nor an automatically controlled internal refresh have taken place, see *Figure 15d*. If a time critical event, or long accesses like page/static column mode can not be interrupted, RFRQ pulsing high can be used to increment a counter. This counter can be used to perform a burst refresh of the number of refreshes missed (through the RFSH input).

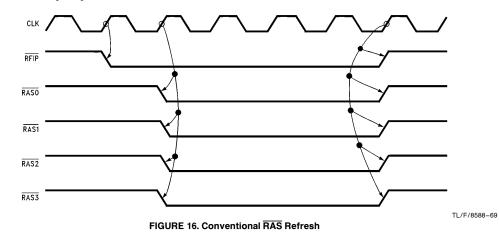

# 5.2 REFRESH CYCLE TYPES

Three different types of refresh cycles are available for use. The three different types are mutually exclusive and can be used with any of the three modes of refresh control. The three different refresh cycle types are: all RAS refresh, staggered RAS refresh and error scrubbing during all RAS refresh. In all refresh cycle types, the RAS precharge time is guaranteed: between the previous access RAS ending and the refresh RAS starting; between terfresh RAS3.

### 5.2.1 Conventional RAS Refresh

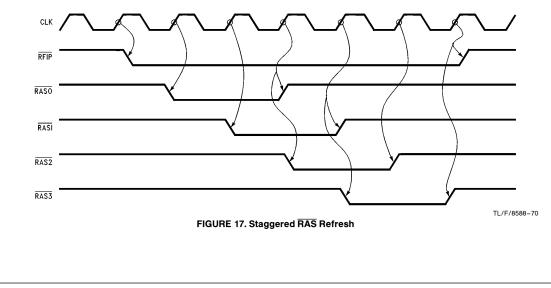

A conventional refresh cycle causes  $\overline{RAS0}$ -3 to all assert from the first positive edge of CLK after  $\overline{RFIP}$  is asserted as shown in *Figure 16*.  $\overline{RAS0}$ -3 will stay asserted until the number of positive edges of CLK programmed have passed. On the last positive edge,  $\overline{RAS0}$ -3, and  $\overline{RFIP}$  will be negated. This type of refresh cycle is programmed by negating address bit R9 during programming.

### 5.2.2 Staggered RAS Refresh

A staggered refresh staggers each RAS or group of RASs by a positive edge of CLK as shown in *Figure 17*. The number of RASs, which will be asserted on each positive edge of CLK, is determined by the RAS, CAS configuration mode programming bits C4–C6. If single RAS outputs are selected during programming, then each RAS will assert on successive positive edges of CLK. If two RAS outputs are selected during programming then RAS0 and RAS1 will assert

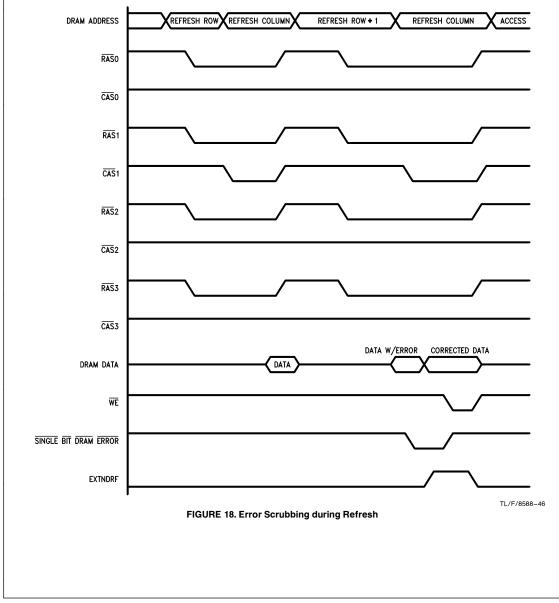

on the first positive edge of CLK after  $\overline{\text{RFIP}}$  is asserted.  $\overline{\text{RAS2}}$  and  $\overline{\text{RAS3}}$  will assert on the second positive edge of CLK after  $\overline{\text{RFIP}}$  is asserted. If all  $\overline{\text{RAS}}$  outputs were selected during programming, all  $\overline{\text{RAS}}$  outputs would assert on the first positive edge of CLK after  $\overline{\text{RFIP}}$  is asserted. Each  $\overline{\text{RAS}}$  or group of  $\overline{\text{RASs}}$  will meet the programmed  $\overline{\text{RAS}}$  low time and then negate.

### 5.2.3 Error Scrubbing during Refresh

The DP8420A/21A/22A support error scrubbing during all RAS DRAM refreshes. Error scrubbing during refresh is selected through bits C4–C6 with bit R9 negated during programming. Error scrubbing can not be used with staggered refresh (see Section 8.0). Error scrubbing during refresh allows a CAS or group of CASs to assert during the all RAS refresh as shown in *Figure 18*. This allows data to be read from the DRAM array and passed through an Error Detection And Correction Chip, EDAC. If the EDAC determines that the data contains a single bit error and corrects that error, the refresh cycle can be extended with the input ex-

tend refresh, EXTNDRF, and a read-modify-write operation can be performed by asserting  $\overline{WE}$ . It is the responsibility of the designer to ensure that  $\overline{WE}$  is negated. The DP8422A has a 24-bit internal refresh address counter that contains the 11 row, 11 column and 2 bank addresses. The DP8420A/21A have a 22-bit internal refresh address counter that contains the 10 row, 10 column and 2 bank addresses. These counters are configured as bank, column, row with the row address as the least significant bits. The bank counter bits are then used with the programming selection to determine which  $\overline{CAS}$  or group of CASs will assert during a refresh.

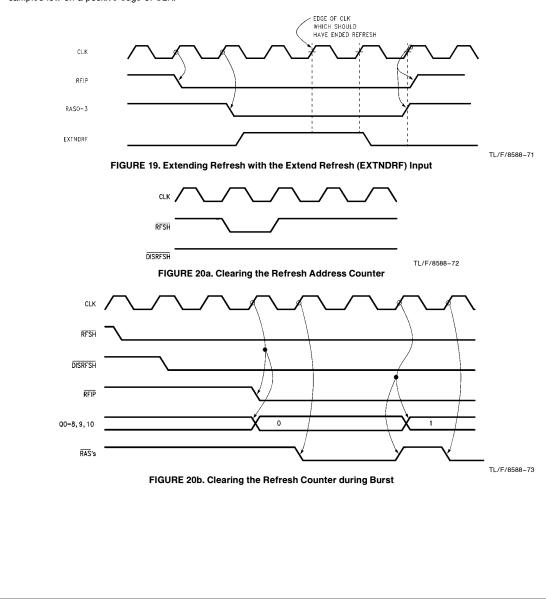

# 5.3 EXTENDING REFRESH

The programmed number of periods of CLK that refresh RASs are asserted can be extended by one or multiple periods of CLK. Only the all RAS (with or without error scrubbing) type of refresh can be extended. To extend a refresh cycle, the input extend refresh, EXTNDRF, must be asserted before the positive edge of CLK that would have negated all the RAS outputs during the refresh cycle and after the positive edge of CLK which starts all RAS outputs during the refresh as shown in *Figure 19*. This will extend the refresh to the next positive edge of CLK and EXTNDRF will be sampled again. The refresh cycle will continue until EXTNDRF is sampled low on a positive edge of CLK.

### 5.4 CLEARING THE REFRESH ADDRESS COUNTER

The refresh address counter can be cleared by asserting RFSH while DISRFSH is negated as shown in *Figure 20a*. This can be used prior to a burst refresh of the entire memory array. By asserting RFSH one period of CLK before DISRFSH is asserted and then keeping both inputs asserted, the DP8420A/21A/22A will clear the refresh address counter and then perform refresh cycles separated by the programmed value of precharge as shown in *Figure 20b*. An end-of-count signal can be generated from the Q DRAM address outputs of the DP8420A/21A/22A and used to negate RFSH.

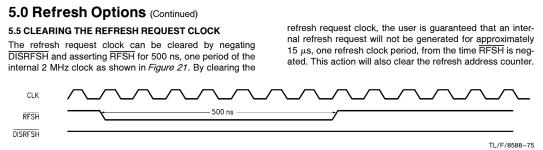

FIGURE 21. Clearing the Refresh Request Clock Counter

# 6.0 Port A Wait State Support

Wait states allow a CPU's access cycle to be increased by one or multiple CPU clock periods. The wait or ready input is named differently by CPU manufacturers. However, any CPU's wait or ready input is compatible with either the WAIT or DTACK output of the DP8420A/21A/22A. The user determines whether to program WAIT or DTACK (R7) and which value to select for WAIT or DTACK (R2, R3) depending upon the CPU used and where the CPU samples its wait input during an access cycle.

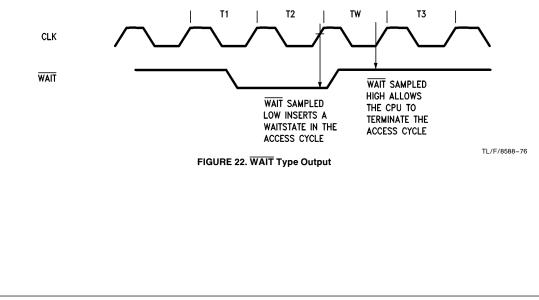

The decision to terminate the CPU access cycle is directly affected by the speed of the DRAMs used. The system designer must ensure that the data from the DRAMs will be present for the CPU to sample or that the data has been written to the DRAM before allowing the CPU access cycle to terminate.

The insertion of wait states also allows a CPU's access cycle to be extended until the DRAM access has taken place. The DP8420A/21A/22A insert wait states into CPU access cycles due to; guaranteeing precharge time, refresh currently in progress, user programmed wait states, the WAITIN signal being asserted and GRANTB not being valid (DP8422A only). If one of these events is taking place and the CPU starts an access, the DP8420A/21A/22A will insert wait states into the access cycle, thereby increasing the length of the CPU's access. Once the event has been completed, the DP8420A/21A/22A will allow the access to take place and stop inserting wait states.

There are six programming bits, R2–R7; an input,  $\overline{\text{WAITIN}}$ ; and an output that functions as  $\overline{\text{WAIT}}$  or  $\overline{\text{DTACK}}$ .

### 6.1 WAIT TYPE OUTPUT

With the R7 address bit negated during programming, the user selects the  $\overline{\text{WAIT}}$  output. As long as  $\overline{\text{WAIT}}$  is sampled asserted by the CPU, wait states (extra clock periods) are inserted into the current access cycle as shown in Figure 22. Once  $\overline{WAIT}$  is sampled negated, the access cycle is completed by the CPU. WAIT is asserted at the beginning of a chip selected access and is programmed to negate a number of positive edges and/or negative levels of CLK from the event that starts the access. WAIT can also be programmed to function in page/burst mode applications. Once  $\overline{\text{WAIT}}$  is negated during an access, and the  $\overline{\text{ECAS}}$ inputs are negated with AREQ asserted, WAIT can be programmed to toggle, following the ECAS inputs. Once AREQ is negated, ending the access, WAIT will stay negated until the next chip selected access. For more details about WAIT Type Output, see Application Note AN-773.

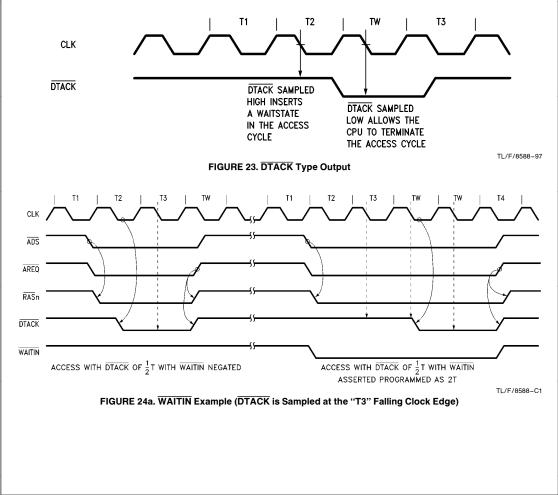

# 6.0 Port A Wait State Support (Continued)

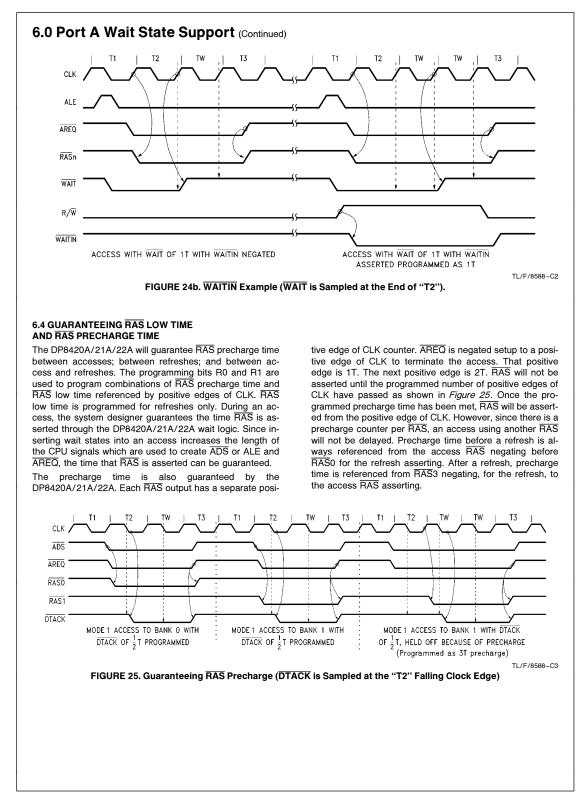

# 6.2 DTACK TYPE OUTPUT

With the R7 address bit asserted during programming, the user selects the DTACK type output. As long as DTACK is sampled negated by the CPU, wait states are inserted into the current access cycle as shown in Figure 23. Once DTACK is sampled asserted, the access cycle is completed by the CPU. DTACK, which is normally negated, is programmed to assert a number of positive edges and/or negative levels from the event that starts RAS for the access. DTACK can also be programmed to function during page/ burst mode accesses. Once DTACK is asserted and the ECAS inputs are negated with AREQ asserted, DTACK can be programmed to negate and assert from the ECAS inputs toggling to perform a page/burst mode operation. Once AREQ is negated, ending the access, DTACK will be negated and stays negated until the next chip selected access. For more details about DTACK type output see Application Note AN-773.

### 6.3 DYNAMICALLY INCREASING THE NUMBER OF WAIT STATES

The user can increase the number of positive edges of CLK before DTACK is asserted or WAIT is negated. With the input WAITIN asserted, the user can delay DTACK asserting or  $\overline{\text{WAIT}}$  negating either one or two more positive edges of CLK. The number of edges is programmed through address bit R6. If the user is increasing the number of positive edges in a delay that contains a negative level, the positive edges will be met before the negative level. For example if the user programmed DTACK of 1/2T, asserting WAITIN, programmed as 2T, would increase the number of positive edges resulting in DTACK of 21/2T as shown in Figure 24a. Similarly, WAITIN can increase the number of positive edges in a page/burst access. WAITIN can be permanently asserted in systems requiring an increased number of wait states. WAITIN can also be asserted and negated, depending on the type of access. As an example, a user could invert the WRITE line from the CPU and connect the output to WAITIN. This could be used to perform write accesses with 1 wait state and read accesses with 2 wait states as shown in Figure 24b.

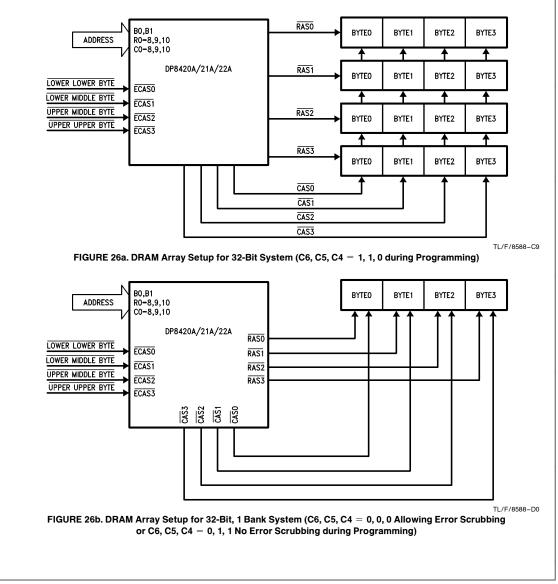

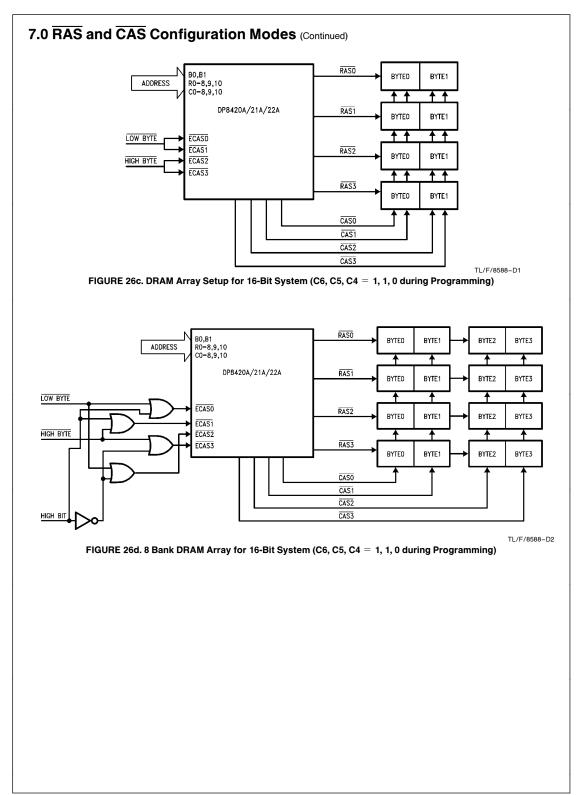

# 7.0 RAS and CAS Configuration Modes

The DP8420A/21A/22A allow the user to configure the DRAM array to contain one, two or four banks of DRAM. Depending on the functions used, certain considerations must be used when determining how to set up the DRAM array. Programming address bits C4, C5 and C6 along with bank selects, BO-1, and CAS enables, ECASO-3, determine which RAS or group of RASs and which CAS or group of CASs will be asserted during an access. Different memory schemes are described. The DP8420A/21A/22A is specified driving a heavy load of 72 DRAMs, representing four banks of DRAM with 16-bit words and 2 parity bits. The DP8420A/21A/22A can drive more than 72 DRAMs, but the AC timing must be increased. Since the RAS and CAS outputs should be used for the maximum amount of drive.

### 7.1 BYTE WRITING

By selecting a configuration in which all  $\overline{CAS}$  outputs are selected during an access, the  $\overline{ECAS}$  inputs enable a single or group of  $\overline{CAS}$  outputs to select a byte (or bytes) in a word size of up to 32 bits. In this case, the  $\overline{RAS}$  outputs are used to select which of up to 4 banks is to be used as shown in *Figures 26a* and *26b*. In systems with a word size of 16 bits, the byte enables can be gated with a high order address bit to produce four byte enables which gives an equivalent to 8 banks of 16-bit words as shown in *Figure 26d*. If less memory is required, each  $\overline{CAS}$  should be used to drive each nibble in the 16-bit word as shown in *Figure 26c*.

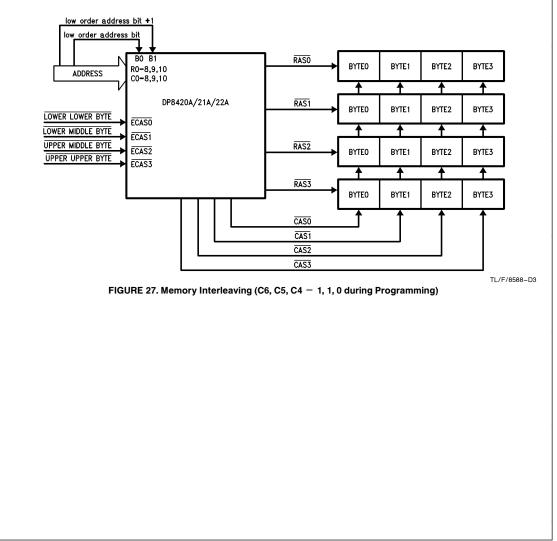

# 7.0 RAS and CAS Configuration Modes (Continued)

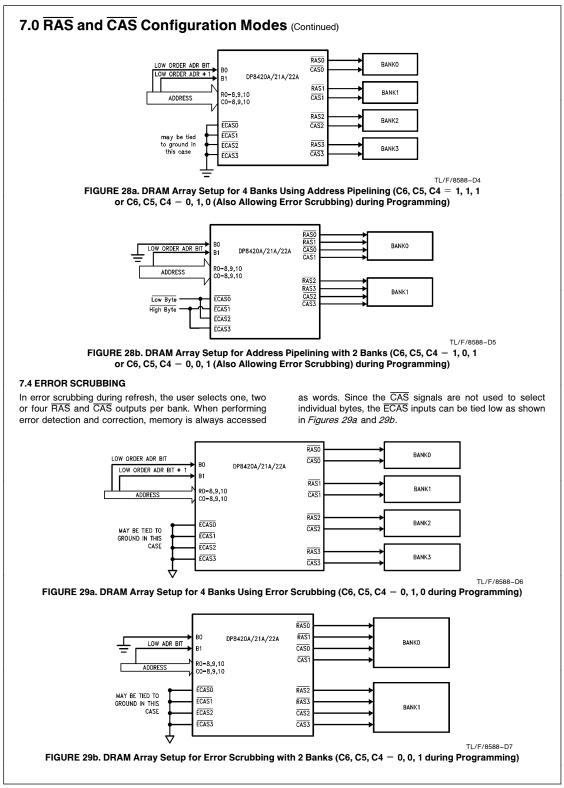

### 7.2 MEMORY INTERLEAVING

Memory interleaving allows the cycle time of DRAMs to be reduced by having sequential accesses to different memory banks. Since the DP8420A/21A/22A have separate precharge counters per bank, sequential accesses will not be delayed if the accessed banks use different RAS outputs. To ensure different RAS outputs will be used, a mode is selected where either one or two RAS outputs will be asserted during an access. The bank select or selects, B0 and B1, are then tied to the least significant address bits, causing a different RAS's to assert during each sequential access as shown in *Figure 27*. In this figure there should be at least one clock period of all RAS's negated between different RAS's being asserted to avoid the condition of a CAS before RAS refresh cycle.

### 7.3 ADDRESS PIPELINING

Address pipelining allows several access RASs to be asserted at once. Because RASs can overlap, each bank requires either a mode where one  $\overline{RAS}$  and one  $\overline{CAS}$  are used per bank as shown in Figure 28a or where two RASs and two CASs are used per bank as shown in Figure 28b. Byte writing can be accomplished in a 16-bit word system if two RASs and two CASs are used per bank. In other systems, WEs (or external gating on the CAS outputs) must be used to perform byte writing. If  $\overline{\text{WEs}}$  are used separate data in and data out buffers must be used. If the array is not layed out this way, a CAS to a bank can be low before RAS, which will cause a refresh of the DRAM, not an access. To take full advantage of address pipelining, memory interleaving is used. To memory interleave, the least significant address bits should be tied to the bank select inputs to ensure that all "back to back" sequential accesses are not delayed, since different memory banks are accessed.

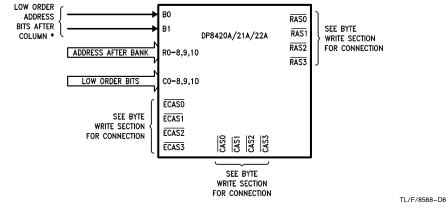

# 7.0 RAS and CAS Configuration Modes (Continued)

# 7.5 PAGE/BURST MODE

In a static column, page or burst mode system, the least significant bits must be tied to the column address in order to ensure that the page/burst accesses are to sequential memory addresses, as shown in *Figure 30*. In a nibble mode system, the least significant bits must be tied to the highest column and row address bits in order to ensure that sequential address bits are the "nibble" bits for nibble mode accesses (*Figure 30*). The ECAS inputs may then be tog-

gled with the DP8420A/21A/22A's address latches in fallthrough mode, while  $\overline{AREQ}$  is asserted. The  $\overline{ECAS}$  inputs can also be used to select individual bytes. When using nibble mode DRAMS, the third and fourth address bits can be tied to the bank select inputs to perform memory interleaving. In page or static column modes, the two address bits after the page size can be tied to the bank select inputs to select a new bank if the page size is exceeded.

\*See table below for row, column & bank address bit map. A0, A1 are used for byte addressing in this example.

Addresses	Nibble Mode*	Pa	Page Mode/Static Column Mode Page Size					
Addresses		256 Bits/Page	512 Bits/Page	1024 Bits/Page	2048 Bits/Page			
Column Address	$\begin{array}{l} \text{C9,R9}=\text{A2,A3}\\ \text{C0-8}=\text{X} \end{array}$	C0-7 = A2-9 C8-10 = X	C0-8 = A2-10 C9,10 = X	C0-9 = A2-11 C10 = X	C0-10 = A2-12			
Row Address	х	x	х	х	х			
B0 B1	A4 A5	A10 A11	A11 A12	A12 A13	A13 A14			

Assume that the least significant address bits are used for byte addressing. Given a 32-bit system A0,A1 would be used for byte addressing.

X = DON'T CARE, the user can do as he pleases.

\*Nibble mode values for R and C assume a system using 1 Mbit DRAMs

FIGURE 30. Page, Static Column, Nibble Mode System

# 8.0 Test Mode

Staggered refresh in combination with the error scrubbing mode places the DP8420A/21A/22A in test mode. In this mode, the 24-bit refresh counter is divided into a 13-bit and 11-bit counter. During refreshes both counters are incremented to reduce test time.

# 9.0 DRAM Critical Timing Parameters

The two critical timing parameters, shown in *Figure 31*, that must be met when controlling the access timing to a DRAM are the row address hold time,  $t_{RAH}$ , and the column address setup time,  $t_{ASC}$ . Since the DP8420A/21A/22A contain a precise internal delay line, the values of these parameters can be selected at programming time. These values will also increase and decrease if DELCLK varies from 2 MHz.

### 9.1 PROGRAMMABLE VALUES OF tRAH AND TASC

The DP8420A/21A/22A allow the values of t<sub>RAH</sub> and t<sub>ASC</sub> to be selected at programming time. For each parameter, two choices can be selected. t<sub>RAH</sub>, the row address hold time, is measured from RAS asserted to the row address starting to change to the column address. The two choices for t<sub>RAH</sub> are 15 ns and 25 ns, programmable through address bit C8.

 $t_{ASC},$  the column address setup time, is measured from the column address valid to  $\overline{CAS}$  asserted. The two choices for  $t_{ASC}$  are 0 ns and 10 ns, programmable through address bit C7.

### 9.2 CALCULATION OF tRAH AND tASC

There are two clock inputs to the DP8420A/21A/22A. These two clocks, DELCLK and CLK can either be tied together to the same clock or be tied to different clocks running asynchronously at different frequencies.

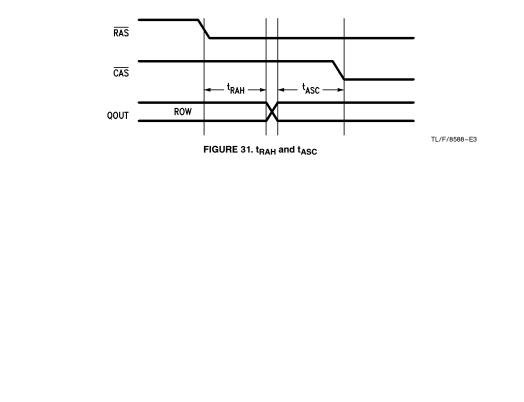

The clock input, DELCLK, controls the internal delay line and refresh request clock. DELCLK should be a multiple of 2 MHz. If DELCLK is not a multiple of 2 MHz,  $t_{RAH}$  and  $t_{ASC}$  will change. The new values of  $t_{RAH}$  and  $t_{ASC}$  can be calculated by the following formulas:

If  $t_{\rm RAH}$  was programmed to equal 15 ns then  $t_{\rm RAH}=30^{*}(((\rm DELCLK\ Divisor)^{*}\ 2\ MHz/(\rm DELCLK\ Frequency))-1)$  + 15 ns.

If  $t_{RAH}$  was programmed to equal 25 ns then  $t_{RAH}=30^{*}(((DELCLK\ Divisor)^{*}\ 2\ MHz/(DELCLK\ Frequency))-1)$   $+\ 25$  ns.

If  $t_{ASC}$  was programmed to equal 0 ns then  $t_{ASC}=15^{\ast}$  ((DELCLK Divisor)\* 2 MHz/(DELCLK Frequency)) - 15 ns. If  $t_{ASC}$  was programmed to equal 10 ns then  $t_{ASC}=25^{\ast}$  ((DELCLK Divisor)\* 2 MHz/(DELCLK Frequency)) - 15 ns. Since the values of  $t_{RAH}$  and  $t_{ASC}$  are increased or decreased, the time to  $\overline{CAS}$  asserted will also increase or decrease. These parameters can be adjusted by the following formula:

Delay to  $\overline{CAS}$  = Actual Spec. + Actual t<sub>RAH</sub> - Programmed t<sub>RAH</sub> + Actual t<sub>ASC</sub> - Programmed t<sub>ASC</sub>.

# 10.0 Dual Accessing (DP8422A)

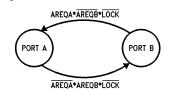

The DP8422A has all the functions previously described. In addition to those features, the DP8422A also has the capabilities to arbitrate among refresh, Port A and a second port, Port B. This allows two CPUs to access a common DRAM array. DRAM refresh has the highest priority followed by the currently granted port. The ungranted port has the lowest priority. The last granted port will continue to stay granted even after the access has terminated, until an access request is received from the ungranted port (see Figure 32a). The dual access configuration assumes that both Port A and Port B are synchronous to the system clock. If they are not synchronous to the system clock they should be externally synchronized (Ex. By running the access requests through several Flip-Flops, see Figure 34a).

### **10.1 PORT B ACCESS MODE**

Port B accesses are initiated from a single input, AREQB. When  $\overline{\text{AREQB}}$  is asserted, an access request is generated. If GRANTB is asserted and a refresh is not taking place or precharge time is not required, RAS will be asserted when AREQB is asserted. Once AREQB is asserted, it must stay asserted until the access is over. AREQB negated, negates  $\overline{RAS}$  as shown in *Figure 32b*. Note that if  $\overline{ECAS0} = 1$  during programming the CAS outputs may be held asserted (beyond RASn negating) by continuing to assert the appropriate ECASn inputs (the same as Port A accesses). If Port B is not granted, the access will begin on the first or second positive edge of CLK after GRANTB is asserted (See R0, R1 programming bit definitions) as shown in Figure 32c, assuming that Port A is not accessing the DRAM (CS, ADS/ ALE and AREQ) and RAS precharge for the particular bank

has completed. It is important to note that for GRANTB to transition to Port B, Port A must not be requesting an access at a rising clock edge (or locked) and Port B must be requesting an access at that rising clock edge. Port A can request an access through  $\overline{\text{CS}}$  and  $\overline{\text{ADS}}/\text{ALE}$  or  $\overline{\text{CS}}$  and AREQ. Therefore during an interleaved access where CS and ADS/ALE become asserted before AREQ from the previous access is negated, Port A will retain GRANTB = 0 whether AREQB is asserted or not.

Since there is no chip select for Port B, AREQB must incorporate this signal. This mode of accessing is similar to Mode 1 accessing for Port A.

TL/F/8588-F9

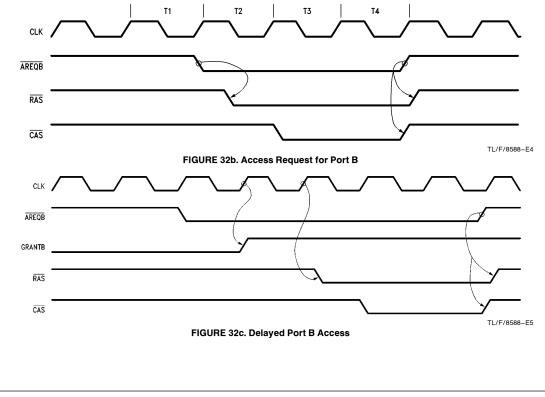

Explanation of Terms

- AREQA = Chip Selected access request from Port A

AREQB = Chip Selected access request from Port B Externally controlled LOCKing of the Port LOCK =

that is currently GRANTed.

# 10.0 Dual Accessing (DP8422A) (Continued)

### **10.2 PORT B WAIT STATE SUPPORT**

Advanced transfer acknowledge for Port B, ATACKB, is used for wait state support for Port B. This output will be asserted when  $\overline{RAS}$  for the Port B access is asserted, as shown in Figures 33a and 33b. Once asserted, this output will stay asserted until AREQB is negated. With external logic, ATACKB can be made to interface to any CPU's wait input as shown in Figure 33c.

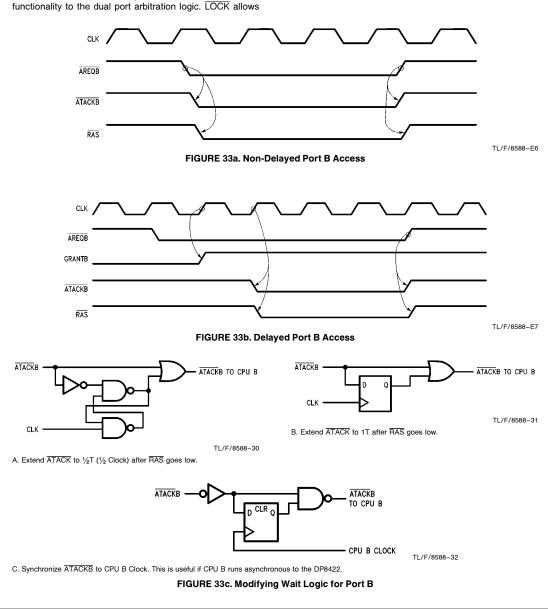

### 10.3 COMMON PORT A AND PORT B DUAL PORT FUNCTIONS

An input, LOCK, and an output, GRANTB, add additional

Port A or Port B to lock out the other port from the DRAM. When a Port is locked out of the DRAM, wait states will be inserted into its access cycle until it is allowed to access memory. GRANTB is used to multiplex the input control signals and addresses to the DP8422A.

### 10.3.1 GRANTB Output

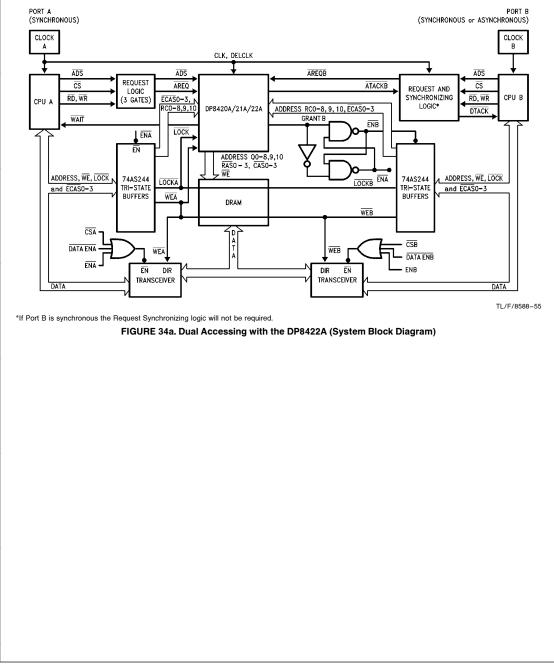

The output GRANTB determines which port has current access to the DRAM array. GRANTB asserted signifies Port B has access. GRANTB negated signifies Port A has access to the DRAM array.

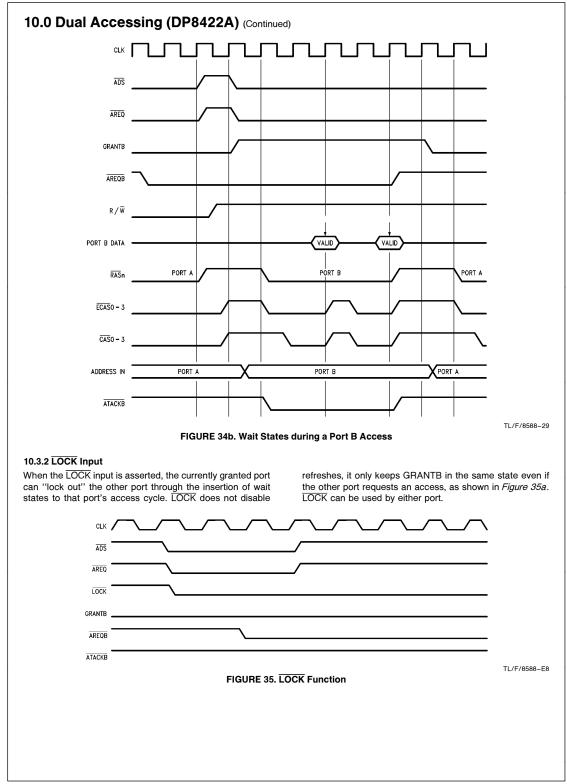

# 10.0 Dual Accessing (DP8422A) (Continued)

Since the DP8422A has only one set of address inputs, the signal is used, with the addition of buffers, to allow the currently granted port's addresses to reach the DP8422A. The signals which need to be bufferred are R0–10, C0–10, B0–1, ECAS0–3, WE, and LOCK. All other inputs are not common and do not have to be buffered as shown in *Figure 34a*. If a Port, which is not currently granted, tries to access

the DRAM array, the GRANTB output will transition from a rising clock edge from  $\overline{AREQ}$  or  $\overline{AREQB}$  negating and will precede the  $\overline{RAS}$  for the access by one or two clock periods. GRANTB will then stay in this state until the other port requests an access and the currently granted port is not accessing the DRAM as shown in *Figure 34b*.

### **13.0 AC Timing Parameters** (Continued)

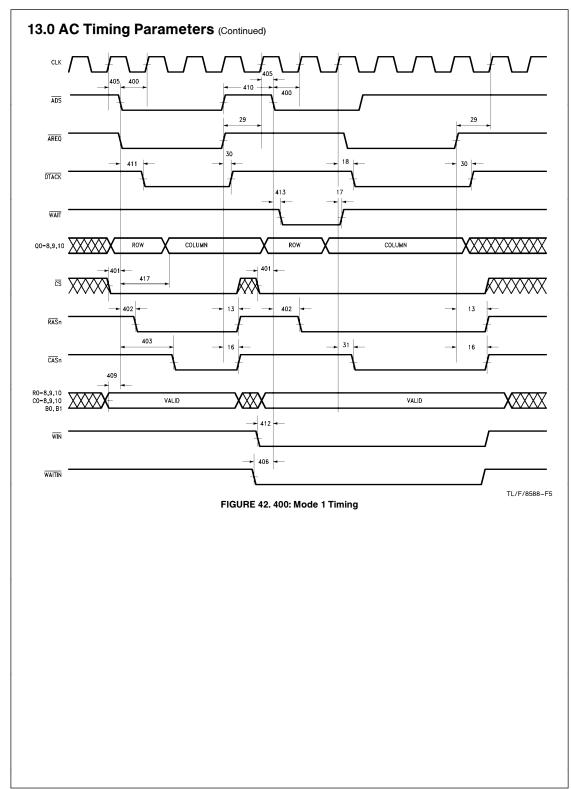

Unless otherwise stated  $V_{CC} = 5.0V \pm 10\%$ , 0°C <  $T_A < 70$ °C, the output load capacitance is typical for 4 banks of 18 DRAMs per bank, including trace capacitance (Note 2).

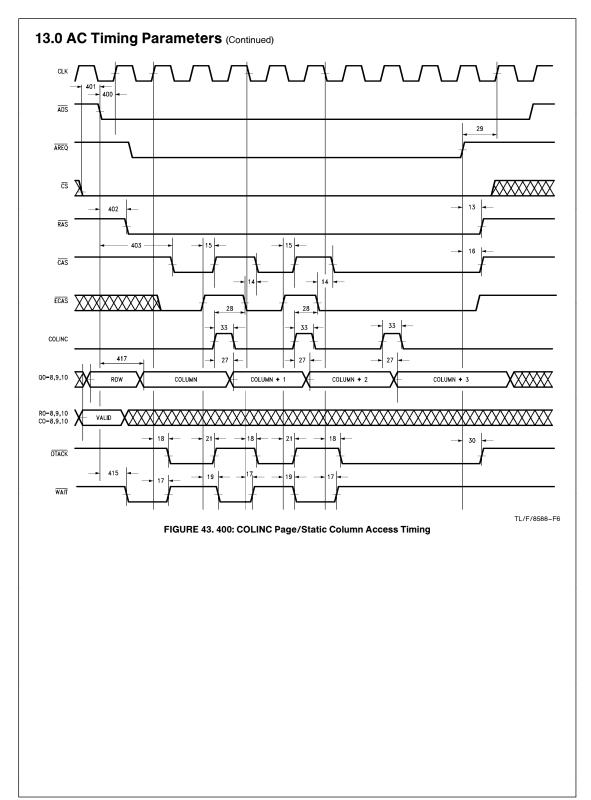

Two different loads are specified:

 $C_L = 50 \text{ pF}$  loads on all outputs except  $C_L = 150 \text{ pF}$  loads on Q0-8, 9, 10 and  $\overline{\text{WE}}$ ; or

 $C_{H}=50$  pF loads on all outputs except  $C_{H}=125$  pF loads on  $\overline{RAS0-3}$  and  $\overline{CAS0-3}$  and  $C_{H}=380$  pF loads on Q0-8, 9, 10 and  $\overline{WE}.$

### FIGURE 44. 500: Programming

# 14.0 Functional Differences between the DP8420A/21A/22A and the DP8420/21/22

# 1. Extending the Column Address Strobe ( $\overline{\text{CAS}}$ ) after $\overline{\text{AREQ}}$ Transitions High

The DP8420A/21A/22A allows  $\overline{CAS}$  to be asserted for an indefinite period of time beyond  $\overline{AREQ}$  (or  $\overline{AREQB}$ , DP8422A only. Scrubbing refreshes are not affected.) being negated by continuing to assert the appropriate  $\overline{ECAS}$ inputs. This feature is allowed as long as the  $\overline{ECAS}$  input was negated during programming. The DP8420/21/22 does not allow this feature.

### 2. Dual Accessing

The DP8420A/21A/22A asserts  $\overline{\text{RAS}}$  either one or two clock periods after GRANTB has been asserted or negated depending upon how the R0 bit was programmed during the mode load operation. The DP8420/21/22 will always start  $\overline{\text{RAS}}$  one clock period after GRANTB is asserted or negated. The above statements assume that  $\overline{\text{RAS}}$  precharge has been completed by the time GRANTB is asserted or negated.

### 3. Refresh Request Output (RFRQ)

The DP8420A/21A/22A allows  $\overline{\text{RFRQ}}$  (refresh request) to be output on the  $\overline{\text{WE}}$  output pin given that  $\overline{\text{ECAS0}}$  was negated during programming or the controller was programmed to function in the address pipelining (memory interleaving) mode. The DP8420/21/22 only allows  $\overline{\text{RFRQ}}$  to be output during the address pipelining mode.

### 4. Clearing the Refresh Request Clock Counter

The DP8420A/21A/22A allows the internal refresh request clock counter to be cleared by negating DISRFSH and asserting RFSH for at least 500 ns. The DP8420/21/22 clears the internal refresh request clock counter if DISRFSH remains low for at least 500 ns. Once the internal refresh request clock counter is cleared the user is guaranteed that an internally generated RFRQ will not be generated for at least 13  $\mu$ s-15  $\mu$ s (depending upon how programming bits C0, 1, 2, 3 were programmed).

# 15.0 DP8420A/21A/22A User Hints

- 1. All inputs to the DP8420A/21A/22A should be tied high, low or the output of some other device.
- Note: One signal is active high. COLINC (EXTNDRF) should be tied low to disable.
- 2. Each ground on the DP8420A/21A/22A must be decoupled to the closest on-chip supply (V<sub>CC</sub>) with 0.1  $\mu$ F ceramic capacitor. This is necessary because these grounds are kept separate inside the DP8420A/21A/22A. The decoupling capacitors should be placed as close as possible with short leads to the ground and supply pins of the DP8420A/21A/22A.
- 3. The output called "CAP" should have a 0.1  $\mu {\rm F}$  capacitor to ground.
- 4. The DP8420A/21A/22A has  $20\Omega$  series damping resistors built into the output drivers of RAS, CAS, address and WE/RFRQ. Space should be provided for external damping resistors on the printed circuit board (or wire-

wrap board) because they may be needed. The value of these damping resistors (if needed) will vary depending upon the output, the capacitance of the load, and the characteristics of the trace as well as the routing of the trace. The value of the damping resistor also may vary between the wire-wrap board and the printed circuit board. To determine the value of the series damping resistor it is recommended to use an oscilloscope and look at the furthest DRAM from the DP8420A/21A/22A. The undershoot of RAS, CAS, WE and the addresses should be kept to less than 0.5V below ground by varying the value of the damping resistor. The damping resistor should be placed as close as possible with short leads to the driver outputs of the DP8420A/21A/22A.

- 5. The circuit board must have a good V<sub>CC</sub> and ground plane connection. If the board is wire-wrapped, the V<sub>CC</sub> and ground pins of the DP8420A/21A/22A, the DRAM associated logic and buffer circuitry must be soldered to the V<sub>CC</sub> and ground planes.
- 6. The traces from the DP8420A/21A/22A to the DRAM should be as short as possible.
- ECAS0 should be held low during programming if the user wishes that the DP8420A/21A/22A be compatible with a DP8420/21/22 design.
- 8. Parameter Changes due to Loading
  - All A.C. parameters are specified with the equivalent load capacitances, including traces, of 64 DRAMs organized as 4 banks of 18 DRAMs each. Maximums are based on worst-case conditions. If an output load changes then the A.C. timing parameters associated with that particular output must be changed. For example, if we changed our output load to
  - C = 250 pF loads on  $\overline{RAS}0-3$  and  $\overline{CAS}0-3$
  - C = 760 pF loads on Q0-9 and  $\overline{WE}$

we would have to modify some parameters (not all calculated here)

\$308a clock to CAS asserted

(t<sub>RAH</sub> = 15 ns, t<sub>ASC</sub> = 0 ns)

A ratio can be used to figure out the timing change per change in capacitance for a particular parameter by using the specifications and capacitances from heavy and light load timing.

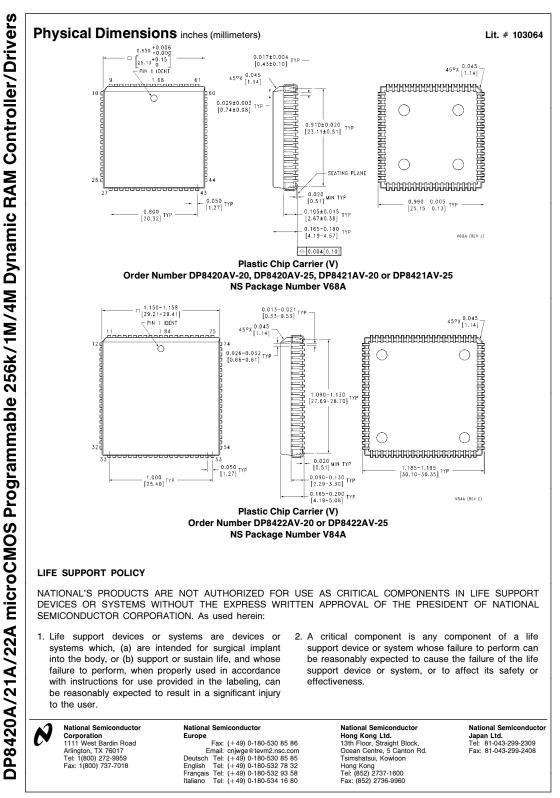

$$\mathsf{Ratio} = \frac{\$308a \text{ w/Heavy Load} - \$308a \text{ w/Light Load}}{\mathsf{C}_{\mathsf{H}}(\overline{\mathsf{CAS}}) - \mathsf{C}_{\mathsf{L}}(\overline{\mathsf{CAS}})}$$

$$= \frac{79 \text{ ns} - 72 \text{ ns}}{125 \text{ pF} - 50 \text{ pF}} = \frac{7 \text{ ns}}{75 \text{ pF}}$$

 $308a (actual) = (capacitance difference \times ratio) + 308a (specified)$ 

= 
$$(250 \text{ pF} - 125 \text{ pF}) \frac{7 \text{ ns}}{75 \text{ pF}} + 79 \text{ ns}$$
  
= 11.7 ns + 79 ns  
= 90.7 ns @ 250 pF load

 It is required that the user perform a hardware reset of the DP8420A/21A/22A before programming and using the chip. A hardware reset consists of asserting both ML and DISRFSH for a minimum of 16 positive edges of CLK, see Section 3.1.
