3.2Gbps Adaptive Equalizer and Cable Driver

MAX3800

General Description

The MAX3800 is a +3.3V adaptive cable equalizer and cable driver implemented together on a single chip. It is designed for coaxial and twin-axial cable point-to-point communications applications. The driver features differential current-mode logic (CML) inputs and outputs as well as adjustable output amplitude. The equalizer includes differential CML data inputs and outputs, a loss-of-signal ($\overline{LOS}$) output, and a cable integrity monitor (CIM) output.

The adaptive cable equalizer is capable of equalizing differential or single-ended signals at data rates up to 3.2Gbps. It automatically adjusts to attenuation caused by skin-effect losses of up to 30dB at 1.6GHz. The equalizer effectively extends the usable length of copper cable in high-frequency interconnect applications.

The MAX3800 is available in a 32-pin TQFP package with exposed pad and consumes only 200mW at +3.3V. The driver can be disconnected from the power supply when it is not needed, resulting in a 40% reduction in supply current.

Applications

High-Speed Links in Communications and Data Systems

Backplane and Interconnect Applications

SDH/SONET Transmission Equipment

Pin Configuration appears at end of data sheet.

Features

♦ **Single +3.3V Operation**

♦ **Typical Power Dissipation = 200mW at +3.3V**

♦ **Data Rates Up to 3.2Gbps**

♦ **Adjustable Cable Driver Output Amplitude**

♦ **Equalizer Automatically Adjusts for Different Cable Lengths**

♦ **0dB to 30dB Equalization at 1.6GHz (3.2Gbps)**

♦ **Loss-of-Signal ($\overline{LOS}$) Indicator**

♦ **Cable Integrity Monitor (CIM)**

♦ **On-Chip Input and Output Terminations**

♦ **Low External Component Count**

♦ **Operating Temperature Range = 0°C to +85°C**
♦ **ESD Protection on Cable Inputs and Outputs**

_____ Detailed Description

The MAX3800 consists of a cable driver (transmitter) and an adaptive cable equalizer (receiver). The driver and equalizer are implemented on the same chip, but they are completely independent.

The Cable Driver

The cable driver accepts differential or single-ended current-mode logic (CML) input data at rates up to 3.2Gbps. The driver output is also implemented using CML. The maximum output amplitude can be adjusted over a typical range of 450mV to 870mV by changing the value of the RMOD resistor between 10kΩ and 20kΩ (this resistor is connected between the RMOD pin and ground).

The Adaptive Cable Equalizer

The adaptive cable equalizer accepts differential CML input data at rates up to 3.2Gbps and is capable of equalizing differential or single-ended signals. It automatically adjusts to attenuation levels of up to 30dB at 1.6GHz (due to skin-effect losses in copper cable). The equalizer consists of a CML input buffer, a loss-of-sig-

nal detector, a flat response amplifier, a skin-effect compensation amplifier, a current-steering network, a dual power-detector feedback loop, an output limiting amplifier, and a CML output buffer (Figure 1).

General Theory of Operation

The shape of the power spectrum of a random bit stream can be described by the square of the sinc function, where sinc f = (sin πf) / πf. For sufficiently long bit patterns (nonrandom bit streams), sinc^2(f) is a good approximation. From the shape of the sinc^2(f) function, we can estimate the ratio of the power densities at any two frequencies. The MAX3800 adaptive equalizer employs this principle by incorporating a feedback loop that continuously monitors the power at two frequencies and dynamically adjusts the equalizer to maintain the correct power ratio.

CML Input and Output Buffers

The input and output buffers are implemented using current-mode logic (CML). Equivalent circuits are shown in Figures 2 and 3. For details on interfacing with

Figure 2. CML Input Equivalent Circuit
Figure 3. CML Output Equivalent Circuit

CML, see Maxim application note HFAN-1.0, *Interfacing Between CML, PECL, and LVDS.*

Flat Response and Skin-Effect Compensation Amplifiers

The buffered input waveform is fed equally to two amplifiers—the flat response amplifier and the skin-effect compensation amplifier. The flat response amplifier has a constant gain over the entire frequency range of the device, and the skin-effect compensation amplifier has a gain characteristic that approximates the inverse of the skin-effect attenuation inherent in copper cable. The skin-effect attenuation, in dB per unit length, is proportional to the square root of the frequency. The output currents from the two amplifiers are supplied to the current-steering network. Note that when $\overline{\text{LOS}}$ asserts low, equalization is minimized.

Current-Steering Network

The function of the current-steering network is to combine adjustable quantities of the output currents from the flat response and skin-effect compensation amplifiers to achieve a desired current ratio. The ratio adjustment is controlled by the dual power-detector feedback loop.

The current-steering network is implemented with a pair of variable attenuators that feed into a current-summing node. The variable attenuators are used to attenuate the output currents of the flat response and skin-effect compensation amplifiers under control of the dual power-detector feedback loop. The outputs of the two attenuators are combined at the summing node and then fed to the output limiting amplifier and the feedback loop.

Dual Power-Detector Feedback Loop

The output of the current-steering network is applied to the inputs of two frequency-specific power detectors. One of the power detectors is tuned to 200MHz and the other is tuned to 600MHz. The outputs of the two power detectors are applied to the inverting (200MHz power detector) and noninverting (600MHz power detector) inputs of the differential loop amplifier. The differential outputs of the loop amplifier control the variable attenuators in the current-steering network.

Output Limiting Amplifier

The output limiting amplifier amplifies the signal from the current-steering network to achieve the specified output voltage swing.

_____*Applications Information*

Refer to Maxim application note HFDN-10.0, *Equalizing Gigabit Copper Cable Links with the MAX3800* (available at *www.maxim-ic.com*) for additional applications information.

Selecting RMOD

The cable driver output amplitude can be adjusted by connecting a resistor with a value from 10kΩ to 20kΩ between the RMOD pin and ground. The exact output amplitude of the driver for a given value of RMOD resistance is dependent on a number of factors. Refer to the *Typical Operating Characteristics* "Cable Driver Output Voltage vs. RMOD" for typical values.

Cable Integrity Monitor (CIM)

The differential CIM output current is directly proportional to the output current of the loop amplifier (which controls the current-steering network—see *Detailed Description*). This is an analog current output that indicates the amount of equalization that is being applied. A convenient way to monitor the CIM current is to connect a 100kΩ resistor from each of the CIM outputs to ground, and then measure the voltage at the CIM pins.

The amount of equalization (and thus the CIM output level) is affected by various factors, including cable type, cable length, signal bandwidth, etc. Refer to the *Typical Operating Characteristics* "CIM Voltage vs. Cable Length" for typical values under specific conditions.

Loss-of-Signal ($\overline{\text{LOS}}$) Output

Loss-of-signal is indicated by the $\overline{\text{LOS}}$ output. A low level on $\overline{\text{LOS}}$ indicates that the equalizer input signal power has dropped below a threshold. The $\overline{\text{LOS}}$ output indicates a loss of signal. When the equalizer no longer detects a signal from the channel, the $\overline{\text{LOS}}$ output goes low. When there is sufficient input voltage to the channel (typically greater that 650mV), $\overline{\text{LOS}}$ is high. The $\overline{\text{LOS}}$ output is suitable for indicating problems with the transmission link caused by, for example, a broken cable, a defective driver, or a lost connection to the equalizer.
MAXIM

MAX3800

Single-Ended Operation

For single-ended operation of the cable driver or equalizer, connect the unused input to ground through a series combination of a capacitor (of equal value to other AC-coupling capacitors) and a 50Ω resistor. Note that the MAX3800 is specified for differential operation.

Layout Considerations

The MAX3800's performance can be significantly affected by circuit-board layout and design. Use good high-frequency design techniques, including minimizing ground inductance and using fixed-impedance transmission lines for the high-frequency data signals. Power-supply decoupling capacitors should be placed as close as possible to V_{CC}.
