

## SiPHY™ OC-48/STM-16 SONET/SDH TRANSCEIVER

### Features

Complete, low-power, high-speed, SONET/SDH transceiver with integrated limiting amp, CDR, CMU, and MUX/DEMUX

- Data rates supported: OC-48/STM-16 through 2.7 Gbps FEC
- Low-power operation 1.2 W (typ)
- DSPLL™ based clock multiplier unit w/ selectable loop filter bandwidths
- Integrated limiting amplifier
- Loss-of-signal (LOS) alarm
- Diagnostic and line loopbacks
- SONET-compliant loop timed operation
- Programmable slicing level and sample phase adjustment
- LVDS/LVPECL compatible interface
- Single supply 1.8 V operation
- 15 x 15 mm BGA package

### Ordering Information:

See page 35.

### Applications

- SONET/SDH transmission systems
- Optical transceiver modules
- SONET/SDH test equipment

### Description

The Si5100 is a complete low-power transceiver for high-speed serial communication systems operating between OC-48 and 2.7 Gbps. The receive path consists of a fully-integrated limiting amplifier, clock and data recovery unit (CDR), and 1:16 deserializer. The transmit path combines a low-jitter clock multiplier unit (CMU) with a 16:1 serializer. The CMU uses Silicon Laboratories' DSPLL technology to provide superior jitter performance while reducing design complexity by eliminating external loop filter components. To simplify BER optimization in long-haul applications, programmable slicing and sample phase adjustment are supported. The Si5100 operates from a single 1.8 V supply over the industrial temperature range (-20 to 85 °C).

**Table 7. Absolute Maximum Ratings**

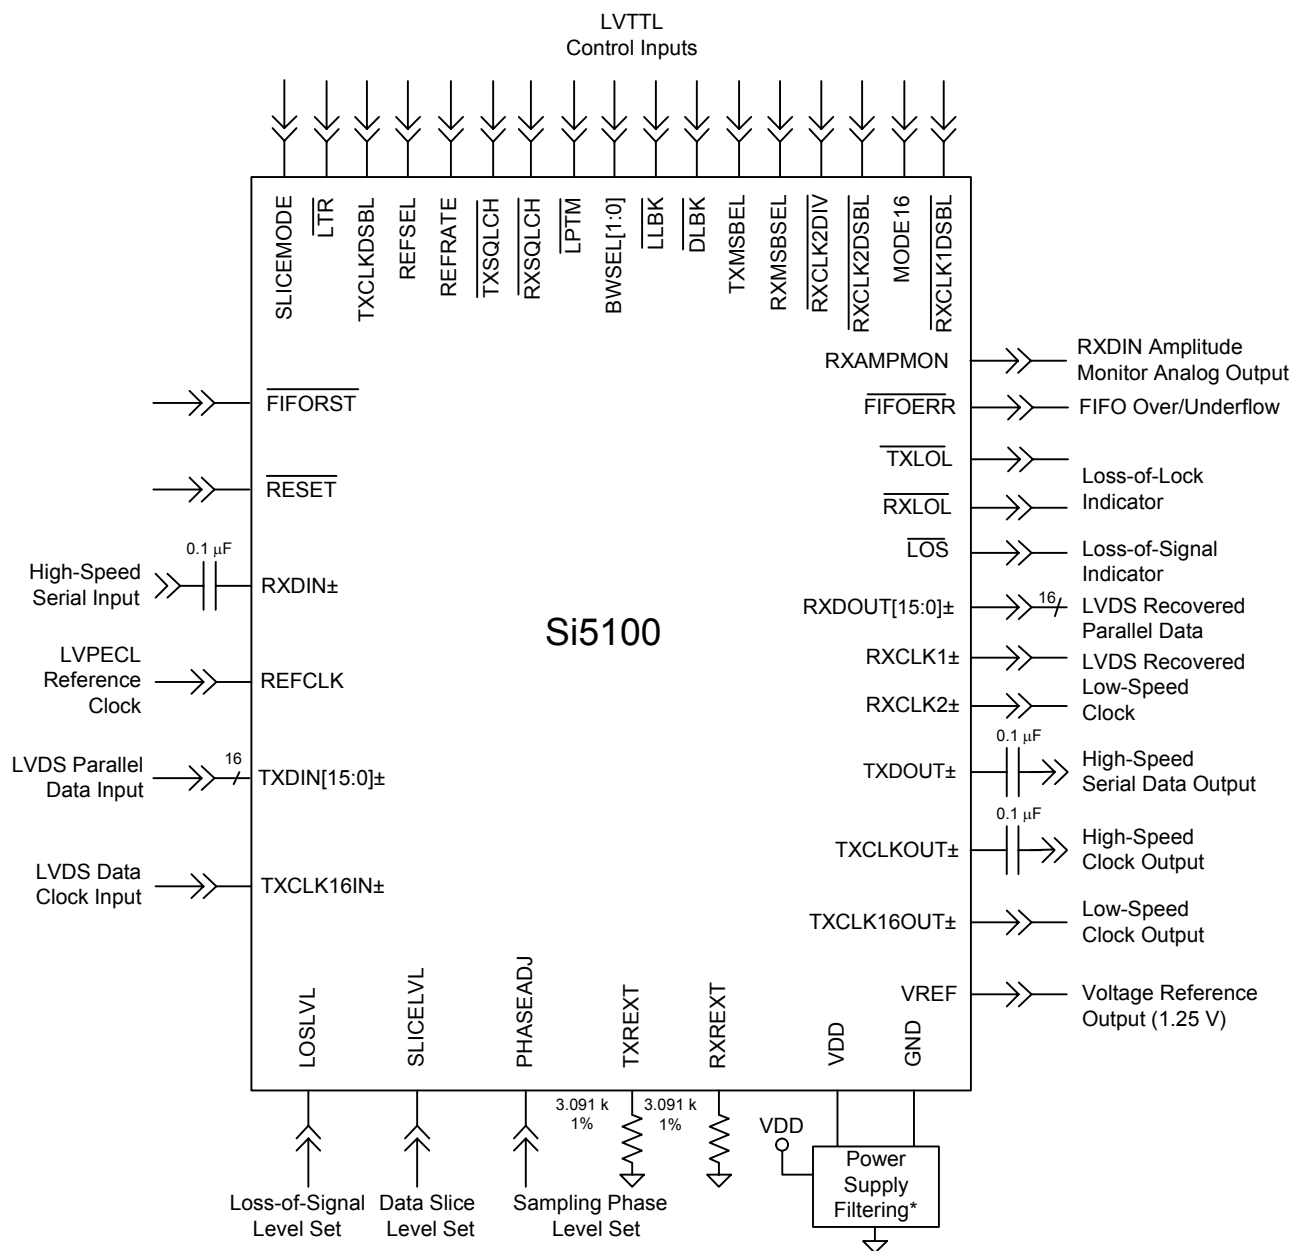

Parameter	Symbol	Value	Unit
DC Supply Voltage	$V_{DD}$	-0.5 to 2.2	V
LVTTTL I/O Supply Voltage	$V_{DDIO}$	-0.5 to 4.0	V
Differential Input Voltage (LVDS Input)	$V_{DIF}$	5	V
Differential Input Voltage (LVDS Output)	$V_{DIF}$	-0.3 to ( $V_{DD} + 0.3$ )	V
Differential Input Voltage (LVTTTL Input)	$V_{DIF}$	2.4	V
Differential Input Voltage (LVTTTL Output)	$V_{DIF}$	5	V
Maximum Current any output PIN		$\pm 50$	mA
Operating Junction Temperature	$T_{JCT}$	-55 to 150	$^{\circ}C$
Storage Temperature Range	$T_{STG}$	-55 to 150	$^{\circ}C$
ESD HBM (2.5 GHz Pins)		1	kV
ESD HBM Tolerance (100 pF, 1.5 k $\Omega$ )		2	kV

**Note:** Permanent device damage can occur if the above Absolute Maximum Ratings are exceeded. Restrict functional operation to the conditions as specified in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods might affect device reliability.

**Table 8. Thermal Characteristics**

Parameter	Symbol	Test Condition	Value	Unit
Thermal Resistance Junction to Ambient	$\varphi_{JA}$	Still Air	20	$^{\circ}C/W$

### 3. Si5100 Typical Application Schematic

**Note\*** See "Power Supply Filtering" on page 21.

## 4. Functional Description

The Si5100 transceiver is a low-power fully-integrated serializer/deserializer that provides significant margin to all SONET/SDH jitter specifications. The device operates from 2.41–2.7 Gbps making it suitable for OC-48/STM-16 applications and OC-48/STM-16 applications that use 255/238 or 255/237 forward error correction (FEC) coding. The low-speed receive/transmit interface uses a low-power parallel LVDS interface compatible with LVPECL.

## 5. Receiver

The receiver within the Si5100 includes a precision limiting amplifier, a jitter-tolerant clock and data recovery unit (CDR), and a 1:16 demultiplexer. Programmable data slicing level and sampling phase adjustment are provided to support bit-error-rate (BER) optimization for long-haul applications.

### 5.1. Receiver Differential Input Circuitry

The receiver serial input provides proper termination and biasing through two resistor dividers internal to the device. The active circuitry has high-impedance inputs and provides sufficient gain for the clock and data recovery unit to recover the serial data. The input bias levels are optimized for jitter tolerance and input sensitivity and are typically not dc compatible with standard I/Os; simply ac couple the data lines as shown in Figure 10 on page 22.

### 5.2. Limiting Amplifier

The Si5100 incorporates a limiting amplifier with sufficient gain to directly accept the output of transimpedance amplifiers.

The limiting amplifier provides sufficient gain to fully saturate with input signals that are greater than 30 mV peak-to-peak differential. In addition, input signals up to 2 V peak-to-peak differential do not cause any performance degradation.

#### 5.2.1. Receiver Signal Amplitude Monitoring

The Si5100 limiting amplifier includes circuitry that monitors the amplitude of the receiver differential input signal (RXDIN). The RXAMPMON output provides an analog output signal that is proportional to the input signal amplitude. The signal is enabled when slice mode is asserted. The voltage on the RXAMPMON output is nominally equal to one-half of the differential peak-to-peak signal amplitude of RXDIN as shown in Equation 1:

$$V_{\text{RXAMPMON}} \approx V_{\text{RXDIN(PP)}} \times .566$$

**Equation 1**

The receiver signal amplitude monitoring circuit is also used in the generation of the loss-of-signal alarm ( $\overline{\text{LOS}}$ ).

#### 5.2.2. Loss-of-Signal Alarm ( $\overline{\text{LOS}}$ )

The Si5100 can be configured to activate a loss-of-signal alarm output ( $\overline{\text{LOS}}$ ) when the RXDIN input amplitude drops below a programmable threshold level. An appropriate level of hysteresis prevents unnecessary switching on  $\overline{\text{LOS}}$ .

The  $\overline{\text{LOS}}$  threshold level is set by applying a dc voltage to the LOSLVL input. The mapping of the voltage on the LOSLVL pin to the  $\overline{\text{LOS}}$  threshold level depends on the state of the SLICEMODE input. (The SLICEMODE input is used to select either absolute slice mode or proportional slice mode operation.)

The LOSLVL mapping for absolute slice mode (SLICEMODE = 0) is given in Figure 4. The linear region of the assert can be approximated by the following equation:

$$V_{\text{LOS}} \approx V_{\text{LOSLVL}} \times .958$$

**Equation 2**

where  $V_{\text{LOS}}$  is the differential PK-PK  $\overline{\text{LOS}}$  threshold referred to the RXDIN input, and  $V_{\text{LOSLVL}}$  is the voltage applied to the LOSLVL pin.

The linear region of the de-assert curve can be approximated by the following equation:

$$V_{\text{LOS}} \approx V_{\text{LOSLVL}} \times .762$$

**Equation 3**

The LOSLVL mapping for proportional slice mode (SLICEMODE = 1) is given in Figure 6 on page 17. The linear region of the assert can be approximated by the following equation:

$$V_{\text{LOS}} \approx V_{\text{LOSLVL}} \times .61$$

**Equation 4**

where  $V_{\text{LOS}}$  is the differential pk-pk  $\overline{\text{LOS}}$  threshold referred to the RXDIN input, and  $V_{\text{LOSLVL}}$  is the voltage applied to the LOSLVL pin.

The linear region of the de-assert curve can be approximated by the following equation:

$$V_{\text{LOS}} \approx V_{\text{LOSLVL}} \times .72$$

**Equation 5**

The  $\overline{\text{LOS}}$  detection circuitry is disabled by tying the LOSLVL input to VREF. This forces the  $\overline{\text{LOS}}$  output high.

### 5.2.3. Slice Level Adjustment

The limiting amplifier allows adjustment of the 0/1 decision threshold, or slice level, to allow optimization of bit-error-rates (BER) for demanding applications, such as long-haul links. The Si5100 provides two different modes of slice level adjustment: Absolute slice mode and proportional slice mode. The mode is selected using the SLICEMODE input.

In either mode, the slice level is set by applying a dc voltage to the SLICELVL input. The mapping of the voltage on the SLICELVL pin to the 0/1 decision threshold voltage (or slice voltage) depends on the selected mode of operation.

The SLICELVL mapping for absolute slice mode (SLICEMODE = 0) is given in Figure 6. The linear region of this curve can be approximated by the following equation:

$$V_{\text{LEVEL}} \approx ((V_{\text{SLICELVL}} - (V_{\text{REF}} \times 0.4)) \times 0.375) - 0.005$$

**Equation 6**

where  $V_{\text{LEVEL}}$  is the effective slice level referred to the RXDIN input,  $V_{\text{SLICELVL}}$  is the voltage applied to the SLICELVL pin, and  $V_{\text{REF}}$  is the reference voltage provided by the Si5100 on the VREF output pin (nominally 1.25 V).

The SLICELVL mapping for proportional slice mode (SLICEMODE = 1) is given in Figure 7 on page 18. The linear region of this curve can be approximated by the following equation:

$$V_{\text{LEVEL}} \approx [(V_{\text{SLICELVL}} - (V_{\text{REF}} \times 0.4)) \times (V_{\text{RXDIN(PP)}} \times 0.95)] - [0.03 \times V_{\text{RXDIN(PP)}}]$$

**Equation 7**

where  $V_{\text{LEVEL}}$  is the effective slice level referred to the RXDIN input;  $V_{\text{SLICELVL}}$  is the voltage applied to the SLICELVL pin;  $V_{\text{REF}}$  is the reference voltage provided by the Si5100 on the VREF output pin, and  $V_{\text{RXDIN(PP)}}$  is the peak-to-peak voltage level of the receive data signal applied to the RXDIN input.

The slice level adjustment function can be disabled by tying the SLICELVL input the VREF. When slice level adjustment is disabled, the effective slice level is set to 0 mV relative to internally biased input common mode voltage for RXDIN.

## 5.3. Clock and Data Recovery (CDR)

The Si5100 uses an integrated CDR to recover clock and data from a non-return to zero (NRZ) signal input on RXDIN. The recovered clock is used to regenerate the incoming data by sampling the output of the limiting amplifier at the center of the NRZ bit period.

### 5.3.1. Sample Phase Adjustment

In applications where data eye distortions are introduced by the transmission medium, it may be desirable to recover data by sampling at a point that is not at the center of the data eye. The Si5100 provides a sample phase adjustment capability that allows adjustment of the CDR sampling phase across the NRZ data period. When sample phase adjustment is enabled, the sampling instant used for data recovery can be moved over a range of approximately  $\pm 22$  ps relative to the center of the incoming NRZ bit period.

The sample phase is set by applying a dc voltage to the PHASEADJ input. The mapping of the voltage present on the PHASEADJ input to the sample phase sampling offset is given in Figure 8 on page 18. The linear region of this curve can be approximated by the following equation:

$$\text{Phase Offset} \approx 85 \text{ ps/V} \times (V_{\text{PHASEADJ}} - (0.4 \times V_{\text{REF}}))$$

**Equation 8**

where Phase Offset is the sampling offset in picoseconds from the center of the data eye;  $V_{\text{PHASEADJ}}$  is the voltage applied to the PHASEADJ pin, and  $V_{\text{REF}}$  is the reference voltage provided by the Si5100 on the VREF output pin (nominally 1.25 V). A positive phase offset adjusts the sampling point to lead the default sampling point (the aligned center of the data eye) and a negative phase offset adjusts the sampling point to lag the default sampling point.

Data recovery using a sampling phase offset is disabled by tying the PHASEADJ input to VREF. This forces a phase offset of 0 ps to be used for data recovery.

### 5.3.2. Receiver Lock Detect

The Si5100 provides lock-detect circuitry that indicates whether the PLL has achieved frequency lock with the incoming data. This circuit compares the frequency of a divided down version of the recovered clock with the frequency of the supplied reference clock. The Si5100 uses either REFCLK or TXCLK16IN as the reference clock input signal depending on the state of the REFSEL input. If the (divided) recovered clock frequency deviates from that of the reference clock by more than the amount specified in Table 5 on page 10, the CDR is declared out of lock, and the loss-of-lock (RXLOL) pin is asserted. In this state, the CDR attempts to reacquire lock with the incoming data stream. During reacquisition, the recovered clock frequency (RXCLK1 and RXCLK2) drifts over a range of approximately  $\pm 1000$  ppm relative to the supplied reference clock unless LTR is asserted. The RXLOL output remains asserted until the frequency of the (divided) recovered clock differs from the reference clock frequency by less

than the amount specified in Table 5 on page 10.

The  $\overline{\text{RXLOL}}$  output is asserted automatically if a valid reference clock is not detected.

The  $\overline{\text{RXLOL}}$  output is also asserted whenever the loss of signal alarm ( $\overline{\text{LOS}}$ ) is active, provided that the  $\overline{\text{LTR}}$  input is set high (i.e. provided that the device is not configured for lock-to-reference mode).

### 5.3.3. Lock-to-Reference

The lock-to-reference ( $\overline{\text{LTR}}$ ) input can be utilized to ensure the presence of a stable output clock during a loss-of-signal alarm ( $\overline{\text{LOS}}$ ). When  $\overline{\text{LTR}}$  is asserted, the CDR is prevented from phase locking to the data signal and the CDR locks the  $\text{RXCLKOUT1}$  and  $\text{RXCLKOUT2}$  outputs to the reference clock. In typical applications, the  $\overline{\text{LOS}}$  output is tied to the  $\overline{\text{LTR}}$  input to force a stable output clock during a loss-of-signal condition.

### 5.4. Deserialization

The Si5100 deserializes the high-speed data from the CDR and outputs the deserialized data on the 16-bit parallel data bus  $\text{RXDOUT}[15:0]$ . The demultiplexer used for deserialization is configured by the  $\text{MODE16}$  pin to output either 4-bit or 16-bit data words on the bus. The data words are output on  $\text{RXDOUT}[15:0]$  with the rising edge of  $\text{RXCLK1}$ . When the demultiplexer is configured to output 4-bit data words, the data is output

on  $\text{RXDOUT}[3:0]$ .

### 5.4.1. Serial Input to Parallel Output Relationship

The Si5100 provides the capability to select the order in which the received serial data is mapped to the parallel output bus  $\text{RXDOUT}[15:0]$ . The mapping of the receive bits to the output data word is controlled by the  $\text{RXMSBSEL}$  input. When  $\text{RXMSBSEL}$  is set low, the first bit received is output on  $\text{RXDOUT0}$ , and the following bits are output in order on  $\text{RXDOUT1}$  through  $\text{RXDOUT15}$  ( $\text{RXDOUT1}$  through  $\text{RXDOUT3}$  if  $\text{MODE16} = 0$ ). When  $\text{RXMSBSEL}$  is set high, the first bit received is output on  $\text{RXDOUT15}$  ( $\text{RXDOUT3}$ ), and the following bits are output in order on  $\text{RXDOUT14}$  ( $\text{RXDOUT2}$ ) through  $\text{RXDOUT0}$ .

### 5.5. Voltage Reference Output

The Si5100 provides an output voltage reference that can be used by external circuitry to set the  $\overline{\text{LOS}}$  threshold, slicing level, or sampling phase adjustment input voltage levels. One possible implementation uses a resistor divider to set the control voltage for the  $\text{LOSLVL}$ ,  $\text{SLICELVL}$ , or  $\text{PHASEADJ}$  inputs. An alternative is the use of a digital-to-analog converters (DACs) to set the control voltages. With this approach,  $\text{VREF}$  is used to set the range of the DAC outputs. The voltage on the  $\text{VREF}$  output is nominally 1.25 V.

Figure 6. Typical SLICELVL Transfer Curve, Absolute Slice Mode (SLICEMODE = 0)

Figure 7. Typical SLICELVL Transfer Curve, Proportional Slice Mode (SLICEMODE = 1)

Figure 8. Typical PHASEADJ Transfer Curve

## 5.6. Auxiliary Clock Output

To support the widest range of system timing configurations, The Si5601/Si5602 provides a primary clock output (RXCLK1) and a secondary clock output (RXCLK2). The RXCLK2 output can be configured to provide a clock that is 1/16th or 1/64th the frequency of the high-speed recovered clock. The divide ratio which determines the RXCLK2 output frequency is selected by RXCLK2DIV.

## 5.7. Receive Data Squelch

During some system error conditions, such as  $\overline{\text{LOS}}$ , it may be desirable to force the receive data output to zero in order to avoid propagation of erroneous data into the downstream electronics. The Si5100 provides a data squelching control input,  $\overline{\text{RXSQLCH}}$ , for this purpose.

When the  $\overline{\text{RXSQLCH}}$  input is low, the data outputs,  $\overline{\text{RXDOUT}}[15:0]$ , are forced to a zero state. The  $\overline{\text{RXSQLCH}}$  input is ignored when the device is operating in diagnostic loopback mode ( $\text{DLBK} = 0$ ).

## 6. Transmitter

The transmitter consists of a low-jitter clock multiplier unit (CMU) with a serializer that operates in either a 16:1 or 4:1 configuration. The CMU uses a phase-locked loop (PLL) architecture based on Silicon Laboratories' proprietary DSPLL technology. This technology generates low jitter clock and data outputs that provide significant margin to the SONET/SDH specifications. The DSPLL architecture also utilizes a digitally-implemented loop filter that eliminates the need for external loop filter components. As a result, sensitive noise coupling nodes that typically degrade jitter performance in crowded PCB environments are removed.

The DSPLL also reduces the complexity and relaxes the performance requirements for reference clock distribution circuitry for OC-48/STM-16 optical port cards. The DSPLL provides selectable wideband and narrowband loop filter settings that allow the jitter attenuation characteristics of the CMU to be optimized for the jitter content of the supplied reference clock. This allows the CMU to operate with reference clocks that have relatively high jitter content.

Unlike traditional analog PLL implementations, the loop filter bandwidth of the Si5100 transmitter CMU is controlled by a digital filter inside the DSPLL circuit allowing the bandwidth to be changed without changing any external component values.

## 6.1. DSPLL™ Clock Multiplier Unit

The Si5100's clock multiplier unit (CMU) uses Silicon Laboratories proprietary DSPLL technology to achieve optimal jitter performance. The DSPLL implementation utilizes a digital signal processing (DSP) algorithm to replace the loop filter commonly found in analog PLL designs. This algorithm processes the phase detector error term and generates a digital control value to adjust the frequency of the voltage-controlled oscillator (VCO). The DSPLL implementation requires no external loop filter components. Eliminating sensitive noise entry points makes the DSPLL implementation less susceptible to board-level noise sources and makes SONET/SDH jitter compliance easier to attain in the application.

The transmit CMU multiplies the frequency of the selected reference clock up to the serial transmit data rate. The  $\overline{\text{TXLOL}}$  output signal provides an indication of the transmit CMU lock status. When the CMU has achieved lock with the selected reference, the  $\overline{\text{TXLOL}}$  output is deasserted (driven high). The  $\overline{\text{TXLOL}}$  signal is asserted, indicating a transmit CMU loss-of-lock condition when a valid clock signal is not detected on the selected reference clock input. The  $\overline{\text{TXLOL}}$  signal is also asserted during the transmit CMU frequency calibration. Calibration is performed automatically when the Si5100 is powered on, when a valid clock signal is detected on the selected reference clock input following a period when no valid clock was present, or when the frequency of the selected reference clock is outside of the transmit CMU's PLL lock range, or after RESET is deasserted.

### 6.1.1. Programmable Loop Filter Bandwidth

The digitally-implemented loop filter allows for four transmit CMU loop bandwidth settings that provide wideband or narrowband jitter transfer characteristics. The filter bandwidth is selected via the  $\overline{\text{BWSEL}}[1:0]$  control inputs. The loop bandwidth choices are listed in Table 6. Unlike traditional PLL implementations, changing the loop filter bandwidth of the Si5100 is accomplished without the need to change external component values.

Lower loop bandwidth settings (Narrowband operation) make the Si5100 more tolerant to jitter on the reference clock source. As a result, circuitry used to generate and distribute the physical layer reference clocks can be simplified without compromising margin to the SONET/SDH jitter specifications.

Higher loop bandwidth settings (Wideband operation) are useful in applications where the reference clock is provided by a low jitter source, such as the Si5364 Clock Synchronization IC or Si5320 Precision Clock

Multiplier/Jitter Attenuator IC. Wideband operation allows the DSPLL to more closely track the precision reference source resulting in the best possible jitter performance.

## 6.2. Serialization

The Si5100 serialization circuitry is comprised of a FIFO and a parallel to serial shift register. The device can be configured to serialize either 4-bit data words input on TXDIN[3:0] or 16-bit data words input on TXDIN[15:0]. The 4-bit or 16-bit configuration is selected using the MODE16 input. Low-speed data on the parallel input bus is latched into the FIFO on the rising edge of TXCLK16IN. Data is clocked out of the FIFO and into the shift register by TXCLK16OUT. The high-speed serial data stream TXDOUT is clocked out of the shift register by TXCLKOUT. The TXCLK16OUT clock is provided as an output signal to support either 4-bit or 16-bit word transfers between the Si5100 and upstream devices using a counter clocking scheme.

### 6.2.1. Input FIFO

The Si5100 transmit FIFO decouples the timing of the data transferred into the FIFO via TXCLK16IN from the data transferred into the shift register via TXCLK16OUT. The FIFO is eight parallel words deep and accommodates static phase delay that may be introduced between TXCLK16OUT and TXCLK16IN in counter clocking schemes. Furthermore, the FIFO accommodates a bounded phase drift, or wander, between TXCLK16IN and TXCLK16OUT of up to three parallel data words.

The FIFO circuitry indicates an overflow or underflow condition by asserting the FIFOERR signal. This output can be used to re-center the FIFO read/write pointers by tying it directly to the FIFORST input.

The FIFORST signal causes re-centering of the FIFO read/write pointers. The Si5100 also automatically re-centers the read/write pointers after the device is powered on, after an external reset via the RESET input, and each time the DSPLL transitions from an out-of-lock state to a locked state (when TXLOL transitions from low to high).

### 6.2.2. Parallel Input To Serial Output Relationship

The Si5100 provides the capability to select the order in which the data received on the parallel input bus, TXDIN[15:0], is transmitted serially on the high-speed serial data output, TXDOUT. Data on the parallel bus is transmitted MSB first or LSB first depending on the setting of the TXMSBSEL input. When TXMSBSEL is set low, TXDIN0 is transmitted first, followed in order by TXDIN1 through TXDIN15 (TXDIN1 through TXDIN3 if MODE16 = 0). When TXMSBSEL is set high, TXDIN15

(TXDIN3) is transmitted first, followed in order by TXDIN14 (TXDIN2) through TXDIN0. This feature can simplify printed circuit board (PCB) routing in applications where ICs are mounted on both sides of the PCB.

### 6.2.3. Transmit Data Squelch

To prevent the transmission of corrupted data into the network, the Si5100 provides a control pin that can be used to force the high-speed serial data output TXDOUT to zero. When the TXSQLCH input is set low, the TXDOUT signal is forced to a zero state. The TXSQLCH input is ignored when the device is in line loopback mode ( $\overline{\text{LLBK}} = 0$ ).

### 6.2.4. Clock Disable

The Si5100 provides a clock disable pin, TXCLKDSBL, that can be used to disable the high-speed serial data clock output, TXCLKOUT. When the TXCLKDSBL pin is asserted, the positive and negative terminals of CLKOUT are internally tied to 1.5 V through 50  $\Omega$  on-chip resistors.

This feature can be used to reduce power consumption in applications that do not use the high-speed transmit data clock.

## 7. Loop Timed Operation

The Si5100 can be configured to provide SONET/SDH compliant loop timed operation. When the LPTM input is set low, the transmit clock and data timing is derived from the CDR recovered clock output. This is achieved by dividing down the recovered clock and using it as a reference source for the transmit CMU. This results in transmit clock and data signals that are locked to the timing recovered from the received data path. A narrow-band loop filter setting is recommended for this mode of operation.

## 8. Diagnostic Loopback

The Si5100 provides a diagnostic loopback mode that establishes a loopback path from the serializer output to the deserializer input. This provides a mechanism for looping back data input via the low-speed transmit interface, TXDIN[15:0], to the low-speed receive data interface, RXDOUT[15:0]. This mode is enabled when the DLBK input is set low.

**Note:** Setting both  $\overline{\text{DLBK}}$  and  $\overline{\text{LLBK}}$  low simultaneously is not supported.

## 9. Line Loopback

The Si5100 provides a line loopback mode that establishes a loopback path from the high-speed receive input to the high-speed transmit output. This provides a mechanism for looping back the high-speed clock and data recovered from RXDIN to the transmit data output, TXDOUT, and clock, TXCLKOUT. This mode is enabled when the  $\overline{\text{LLBK}}$  input is set low.

**Note:** Setting both  $\overline{\text{DLBK}}$  and  $\overline{\text{LLBK}}$  low simultaneously is not supported.

## 10. Bias Generation Circuitry

The Si5100 uses two external resistors, RXREXT and TXREXT, to set internal bias currents for the receive and transmit sections of the device, respectively. The external resistors allow precise generation of bias currents, which can significantly reduce power consumption. The bias generation circuitry requires two 3.09 k $\Omega$  (1%) resistors each connected between RXREXT and GND and between TXREXT and GND.

## 11. Reference Clock

The Si5100 supports operation with one of two possible reference clock sources. In the first configuration, an external reference clock is connected to the REFCLK input. The second configuration uses the parallel data clock, TXCLK16IN, as the reference clock source. The REFSEL input is used to select whether the REFCLK or the TXCLK16IN input are used as the reference clock.

When REFCLK is selected as the reference clock source (REFSEL = 1), two possible reference clock frequencies are supported. The reference clock frequency provided on the REFCLK input can be either 1/16th or 1/32th the desired transceiver data rate. The REFCLK frequency is selected using the REFRATE input.

The TXCLK16IN clock frequency is equal to either 1/4th or 1/16th the transceiver data rate depending on the state of the MODE16 input. When TXCLK16IN is selected as the reference clock source (REFSEL = 0), the REFRATE input has no effect.

The CMU in the Si5100's transmit section multiplies the provided reference up to the serial transmit data rate. When the CMU has achieved lock with the selected reference, the TXLOL output is deasserted (driven high).

The CDR in the receive section of the Si5100 uses the selected reference clock to center the receiver PLL frequency in order to speed lock acquisition. When the receive CDR locks to the data input, the RXLOL signal is deasserted (driven high).

## 12. Reset

The Si5100 is reset by holding the  $\overline{\text{RESET}}$  pin low for at least 1  $\mu\text{s}$ . When  $\overline{\text{RESET}}$  is asserted, the input FIFO pointers are reset and the digital control circuitry is initialized.

When  $\overline{\text{RESET}}$  transitions high to start normal operation, the transmit CMU calibration is performed.

## 13. Transmit Differential Output Circuitry

The Si5100 utilizes a current-mode logic (CML) architecture to drive the high-speed serial output clock and data on TXCLKOUT and TXDOUT. An example of output termination with ac coupling is shown in Figure 9. In applications with direct dc coupling, the 0.1  $\mu\text{F}$  capacitors can be omitted. The differential peak-to-peak voltage swing of the CML architecture is listed in Table 2.

## 14. Internal Pullups and Pulldowns

On-chip 30 k $\Omega$  resistors are used to individually set the LVTTTL inputs if these inputs are left unconnected. The specific default state of each input is enumerated in "Pin Descriptions: Si5100" on page 26.

## 15. Power Supply Filtering

The transmitter-generated jitter is most sensitive to power supply noise below its PLL loop-bandwidth (BWSEL setting). The power supply noise of interest is bounded between the SONET/SDH generated jitter specification of 12 kHz (for 2.48832 Gbps) and the PLL loop-bandwidth. Integrated supply noise from 1/10th the SONET/SDH specification (1.2 kHz) to 10x the loop-bandwidth should be suppressed to a level appropriate for each design. Below the PLL loop-bandwidth, the typical generated jitter due to supply noise is approximately 2.5 mUIpp per 1 mVrms; this parameter can be used as a guideline for calculating the output jitter and supply filtering requirements. The receiver does not place additional power supply constraints beyond those listed for the transmitter.

## 17. Pin Descriptions: Si5100

Alphabetically listed by name

Pin Number(s)	Name	I/O	Signal Level	Description
M10 M7	BWSEL1 BWSEL0	I	LVTTTL	<b>Transmit DSPLL Bandwidth Select.</b> The inputs select loop bandwidth of the Transmit Clock Multiplier DSPLL as listed in Table 6. <b>Note:</b> Both inputs have an internal pulldown.
F12	$\overline{\text{DLBK}}$	I	LVTTTL	<b>Diagnostic Loopback.</b> When this input is low, the transmit clock and data are looped back for output on RXDOUT, RXCLK1 and RXCLK2. This pin should be held high for normal operation. <b>Note:</b> This input has an internal pullup.
K3	$\overline{\text{FIFOERR}}$	O	LVTTTL	<b>FIFO Error.</b> This output is asserted (driven low) when a FIFO overflow/underflow has occurred. This output is low until reset by asserting FIFORST.
M6	$\overline{\text{FIFORST}}$	I	LVTTTL	<b>FIFO RESET.</b> When this input is low, the read/write FIFO pointers are reset to their initial state. <b>Note:</b> This input has an internal pullup.
B1, C1–2, D2, D5–11, E4, E11, E2, F11, F1–2, G11, G2, H11, H2, J11, J1–4, K11, K2, L5–11, L2, M1–4	GND	GND		<b>Supply Ground.</b> Connect to system GND. Ensure a very low impedance path for optimal performance.
H12	$\overline{\text{LLBK}}$	I	LVTTTL	<b>Line Loopback.</b> When this input is low, the recovered clock and data are looped back for output on TXDOUT, and TXCLKOUT. Set this pin high for normal operation. <b>Note:</b> This input has an internal pullup.
G3	$\overline{\text{LOS}}$	O	LVTTTL	<b>Loss-of-Signal.</b> This output is asserted (driven low) when the peak-to-peak signal amplitude on RXDIN is below the threshold set via LOSLVL.
C3	LOSLVL	I		<b>LOS Threshold Level.</b> Applying an analog voltage to this pin allows adjustment of the Threshold used to declare $\overline{\text{LOS}}$ . Tying this input to $\overline{\text{VREF}}$ disables $\overline{\text{LOS}}$ detection and forces the $\overline{\text{LOS}}$ output high.

Pin Number(s)	Name	I/O	Signal Level	Description
J12	$\overline{\text{LPTM}}$	I	LVTTTL	<p><b>Loop Timed Operation.</b> When this input is set low, the recovered clock from the receiver is divided down and used as the reference source for the transmit CMU. The narrowband setting for the DSPLL CMU is sufficient to provide SONET compliant jitter generation and jitter transfer on the transmit data and clock outputs (TXDOUT, TXCLKOUT). Set this pin high for normal operation. <b>Note:</b> This input has an internal pullup.</p>
E3	$\overline{\text{LTR}}$	I	LVTTTL	<p><b>Lock-to-Reference.</b> When the <math>\overline{\text{LTR}}</math> input is set low, the receiver PLL locks to the selected reference clock. This function can be used to force a stable output clock on the RXCLK1 and RXCLK2 outputs when no valid input data signal is applied to RXDIN. When the <math>\overline{\text{LTR}}</math> input is set high, the receiver PLL locks to the RXDIN signal (normal operation). <b>Note:</b> This input has an internal pullup.</p>
G12	MODE16	I	LVTTTL	<p><b>MUX/DEMUX Mode.</b> This input configures the multiplexer/demultiplexer to operate with either 4-bit or 16-bit parallel data words. When this input is set high, the device is configured for 16-bit parallel word transfers on RXDOUT[15:0] and TXDIN[15:0]. When this input is set low, the multiplexer/demultiplier operates with 4-bit word transfers on RXDOUT[3:0] and TXDIN[3:0].</p>
D4	PHASEADJ	I		<p><b>Sampling Phase Adjust.</b> Applying an analog voltage to this pin allows adjustment of the sampling phase across the data eye. Tying this input to VREF nominally centers the sampling phase.</p>
G14 H14	REFCLK+ REFCLK-	I	LVPECL	<p><b>Differential Reference Clock.</b> This input is used as the Si5100 reference clock when the REFSEL input is set high (REFSEL = 1). The reference clock sets the operating frequency of the Si5100 transmit CMU, which is used to generate the high-speed transmit clock TXCLKOUT. The reference clock is also used by the Si5100 receiver CDR to center the PLL during lock acquisition, and as a reference for determination of the receiver lock status. The REFCLK frequency is either 1/16th or 1/32nd of the serial data rate (nominally 155 or 78 MHz, respectively). The REFCLK frequency is selected using the REFRATE input.</p>

Pin Number(s)	Name	I/O	Signal Level	Description
H4	REFRATE	I	LVTTTL	<p><b>Reference Clock Rate Select.</b></p> <p>The REFRATE input sets the frequency for the REFCLK input. When REFRATE is set high, the REFCLK frequency is 1/16th the serial data rate (nominally 155 MHz). When REFRATE is set low, the REFCLK frequency is 1/32nd the serial data rate (nominally 78 MHz).</p> <p>The REFRATE input has no effect when the REFSEL input is set low.</p> <p><b>Note:</b> This input has an internal pullup.</p>
L12	REFSEL	I	LVTTTL	<p><b>Reference Clock Selection.</b></p> <p>This input selects the reference clock source to be used by the Si5100 transmitter and receiver. The reference clock sets the operating frequency of the Si5100 transmit CMU, which is used to generate the high-speed transmit clock TXCLKOUT. The reference clock is also used by the Si5100 receiver CDR to center the PLL during lock acquisition, and as a reference for determination of the receiver lock status.</p> <p>When REFSEL = 0, the low-speed data input clock, TXCLK16IN, is used as the reference clock. When REFSEL = 1, the reference clock provided on REFCLK is used.</p> <p><b>Note:</b> This input has an internal pullup.</p>
G4	$\overline{\text{RESET}}$	I	LVTTTL	<p><b>Device Reset.</b></p> <p>Forcing this input low for a at least 1 <math>\mu\text{s}</math> causes a device reset. For normal operation, this pin should be held high.</p> <p><b>Note:</b> This input has an internal pullup.</p>
C6–7, D3, K4, L4, M8, M11	RSVD_GND			<p><b>Reserved Tie to Ground.</b></p> <p>Must be connected directly to GND for proper operation.</p>
C10	RXAMPMON	O	Analog	<p><b>Receiver Amplitude Monitor.</b></p> <p>The RXAMPMON output provides an analog output signal that is proportional to the input signal amplitude. See Equation 1 for the relationship between the RXAMPMON output and RXDIN input. This signal is active when SLICEMODE is asserted.</p>
A2 A3	RXCLK1+ RXCLK1–	O	LVDS	<p><b>Differential Receiver Clock Output 1.</b></p> <p>The clock recovered from the signal present on RXDIN is divided down to the parallel output word rate and output on RXCLK1. In the absence of data, a stable clock on RXCLK1 can be maintained by asserting LTR.</p>

Pin Number(s)	Name	I/O	Signal Level	Description
B2 B3	RXCLK2+ RXCLK2-	O	LVDS	<b>Differential Receiver Clock Output 2.</b> An auxiliary output clock is provided on this pin that is equivalent to, or a submultiple of, the output word rate. The divide factor used in generating RXCLK2 is set via RXCLK2DIV.
C12	$\overline{\text{RXCLK2DIV}}$	I	LVTTTL	<b>RXCLK2 Clock Divider Select.</b> This input selects the divide factor used to generate the RXCLK2 output. When this input is driven high, RXCLK2 is equal to the output word rate on RXDOUT. When driven low, RXCLK2 is 1/4th the output word rate. <b>Note:</b> This input has an internal pullup.
F4	$\overline{\text{RXCLK1DSBL}}$	I	LVTTTL	<b>RXCLK1 Disable.</b> Setting this input low disables the RXCLK1 output. This is used to save power in applications that do not require the primary output clock. <b>Note:</b> This input has an internal pullup.
C8	$\overline{\text{RXCLK2DSBL}}$	I	LVTTTL	<b>RXCLK2 Disable.</b> Setting this input low disables the RXCLK2 output. This saves power in applications that do not require an auxiliary clock. <b>Note:</b> This input has an internal pullup.
D1 E1	RXDIN+ RXDIN-	I	High-Speed Differential	<b>Differential Receive Data Input.</b> The receive clock and data signals RXCLK1, RXCLK2, and RXDOUT[15:0] are recovered from the high-speed data signal present on these pins.

Pin Number(s)	Name	I/O	Signal Level	Description
G13 H13 E14 F14 E13 F13 C14 D14 C13 D13 A14 B14 B12 B13 A12 A13 B10 B11 A10 A11 B8 B9 A8 A9 B6 B7 A6 A7 B4 B5 A4 A5	RXDOUT15+ RXDOUT15- RXDOUT14+ RXDOUT14- RXDOUT13+ RXDOUT13- RXDOUT12+ RXDOUT12- RXDOUT11+ RXDOUT11- RXDOUT10+ RXDOUT10- RXDOUT9+ RXDOUT9- RXDOUT8+ RXDOUT8- RXDOUT7+ RXDOUT7- RXDOUT6+ RXDOUT6- RXDOUT5+ RXDOUT5- RXDOUT4+ RXDOUT4- RXDOUT3+ RXDOUT3- RXDOUT2+ RXDOUT2- RXDOUT1+ RXDOUT1- RXDOUT0+ RXDOUT0-	O	LVDS	<b>Differential Parallel Receive Data Output.</b> The data recovered from the signal present on RXDIN is demultiplexed and output as a 16-bit parallel word via RXDOUT[15:0]. The bit order for demultiplexing is selected by the RXMSBSEL input. The RXDOUT[15:0] outputs are aligned to the rising edge of RXCLK1.
F3	$\overline{\text{RXLOL}}$	O	LVTTTL	<b>Receiver Loss-of-Lock.</b> This output is asserted (driven low) when the recovered clock frequency deviates from the reference clock by the amount specified in Table 5 on page 10 (LOL).

Pin Number(s)	Name	I/O	Signal Level	Description
D12	RXMSBSEL	I	LVTTTL	<p><b>Receive Data Bus Bit Order Select.</b></p> <p>This determines the order of the received data bits on the output bus.</p> <p>When RXMSBSEL is set low, the first bit received is output on RXDOUT0 and the following bits are output in order on RXDOUT1 through RXDOUT15 (RXDOUT1 through RXDOUT3 if MODE16 = 0). When RXMSBSEL is set high, the first bit received is output on RXDOUT15 (RXDOUT3) and the following bits are output in order on RXDOUT14 (RXDOUT2) through RXDOUT0.</p> <p><b>Note:</b> This input has an internal pulldown.</p>
C11	RXREXT			<p><b>Receiver External Bias Resistor.</b></p> <p>This resistor is used by the receiver circuitry to establish bias currents within the device. This pin must be connected to GND through a 3.09 k<math>\Omega</math> (1%) resistor.</p>
C9	$\overline{\text{RXSQLCH}}$	I	LVTTTL	<p><b>Receiver Data Squelch.</b></p> <p>When this input is low the data on RXDOUT[15:0] is forced to a zero state. Set <math>\overline{\text{RXSQLCH}}</math> high for normal operation.</p> <p>The <math>\overline{\text{RXSQLCH}}</math> input is ignored when operating in diagnostic loopback mode (DLBK = 0).</p> <p><b>Note:</b> This input has an internal pullup.</p>
C4	SLICELVL	I		<p><b>Slicing Level Adjustment.</b></p> <p>Applying an analog voltage to this pin allows adjustment of the slicing level applied to the input data eye. Tying this input to VREF sets the slicing offset to 0.</p>
E12	SLICEMODE	I	LVTTTL	<p><b>Slice Level Adjustment Mode.</b></p> <p>The SLICEMODE input is used to select the mode of operation for slicing level adjustment. When SLICEMODE = 0, absolute slice mode is selected. When SLICEMODE = 1, proportional slice mode is selected.</p> <p><b>Note:</b> This input has an internal pulldown.</p>
N2 N1	TXCLK16IN+ TXCLK16IN-	I	LVDS	<p><b>Differential Transmit Data Clock Input.</b></p> <p>The rising edge of this input clocks data present on TXDIN into the device. TXCLK 16IN is also used as the Si5100 reference clock when the REFSEL input is set low.</p>

# Si5100

Pin Number(s)	Name	I/O	Signal Level	Description
P2 P1	TXCLK16OUT+ TXCLK16OUT-	O	LVDS	<b>Divided Down Transmit Output Clock.</b> This clock output is generated by dividing down the high-speed output clock, TXCLKOUT, to match the TXDOUT[15:0] word rate. This is accomplished by dividing by either 4 or 16, depending on the state of the MODE16 input. The TXCLK16OUT is provided for use in counter clocking schemes that transfer data between the system framer and the Si5100. (See REFSEL and REFRATE descriptions.)
K12	TXCLKDSBL	I	LVTTTL	<b>High-Speed Transmit Clock Disable.</b> When this input is high, the output driver for TXCLKOUT is disabled. In applications that do not require the output data clock, the output clock driver should be disabled to save power. <b>Note:</b> This input has an internal pulldown.
G1 H1	TXCLKOUT+ TXCLKOUT-	O	CML	<b>High-Speed Transmit Clock Output.</b> The high-speed output clock, TXCLKOUT, is generated by the PLL in the clock multiplier unit. Its frequency is nominally 16 or 32 times the selected reference source.

Pin Number(s)	Name	I/O	Signal Level	Description
J13 K13 J14 K14 L13 M13 L14 M14 N14 N13 P14 P13 N12 N11 P12 P11 N10 N9 P10 P9 N8 N7 P8 P7 N6 N5 P6 P5 N4 N3 P4 P3	TXDIN15+ TXDIN15- TXDIN14+ TXDIN14- TXDIN13+ TXDIN13- TXDIN12+ TXDIN12- TXDIN11+ TXDIN11- TXDIN10+ TXDIN10- TXDIN9+ TXDIN9- TXDIN8+ TXDIN8- TXDIN7+ TXDIN7- TXDIN6+ TXDIN6- TXDIN5+ TXDIN5- TXDIN4+ TXDIN4- TXDIN3+ TXDIN3- TXDIN2+ TXDIN2- TXDIN1+ TXDIN1- TXDIN0+ TXDIN0-	I	LVDS	<b>Differential Parallel Transmit Data Input.</b> The 4-bit or 16-bit data word present on these pins is multiplexed into a high-speed serial stream and output on TXDOUT. The data word size is set by the MODE16 input. The bit order for transmit multiplexing is selected by the TXMSBSEL input. The data on TXDIN[15:0] is clocked into the device by the rising edge of TXCLK16IN.
K1 L1	TXDOUT+ TXDOUT-	O	CML	<b>Differential High-Speed Transmit Data Output.</b> The 4-bit or 16-bit word input on TXDIN[15:0] is multiplexed into a high-speed serial stream that is output on the TXDOUT pins. The data word size is set by the MODE16 input. The bit order for transmit multiplexing is selected by the TXMSBSEL input. The TXDOUT outputs are updated by the rising edge of TXCLKOUT.
M5	$\overline{\text{TXLOL}}$	O	LVTTTL	<b>Transmit CMU Loss-of-Lock.</b> The $\overline{\text{TXLOL}}$ output is asserted (low) when the CMU is not phase-locked to the selected reference source or if REFCLK is not present. See LOL in Table 5 on page 10.

Pin Number(s)	Name	I/O	Signal Level	Description
M9	TXMSBSEL	I	LVTTL	<p><b>Transmit Data Bus Bit Order Select.</b></p> <p>This input determines the order in which data bits received on the TXDIN[15:0] bus are transmitted on the high-speed serial output TXDOUT. For TXMSBSEL = 0, data on TXDIN0 is transmitted first followed by TXDIN1 through TXDIN15 (TXDIN1 through TXDOUT3 if MODE16 = 0). For TXMSBSEL = 1, TXDIN15 (TXDIN3) is transmitted first followed by TXDIN14 (TXDIN2) through TXDIN0.</p> <p><b>Note:</b> This input has an internal pulldown.</p>
L3	TXREXT			<p><b>Transmitter External Bias Resistor.</b></p> <p>This resistor is used by the transmitter circuitry to establish bias currents within the device. This pin must be connected to GND through a 3.09 k<math>\Omega</math> (1%) resistor.</p>
M12	$\overline{\text{TXSQLCH}}$	I	LVTTL	<p><b>Transmit Data Squelch.</b></p> <p>When <math>\overline{\text{TXSQLCH}}</math> is set low, the output data stream on TXDOUT is forced to a zero state. Set <math>\overline{\text{TXSQLCH}}</math> high for normal operation. The <math>\overline{\text{TXSQLCH}}</math> input is ignored when operating in line loopback mode (LLBK = 0).</p> <p><b>Note:</b> This input has an internal pullup.</p>
E5–10, F5–10, G5–10, H5–10, J5–10, K5–10	V <sub>DD</sub>	V <sub>DD</sub>	1.8 V	<p><b>Supply Voltage.</b></p> <p>Nominally 1.8 V.</p>
H3	V <sub>DDIO</sub>	V <sub>DDIO</sub>	1.8 V or 3.3 V	<p><b>LVTTL I/O Supply Voltage.</b></p> <p>Connect to either 1.8 or 3.3 V. When connected to 3.3 V, LVTTL compatible voltage swings are supported on the LVTTL inputs and LVTTL outputs of the device.</p>
C5	VREF	O	Voltage Ref	<p><b>Voltage Reference.</b></p> <p>The Si5100 provides an output voltage reference that can be used by an external circuit to set the LOS threshold, slicing level, or sampling phase adjustment. The equivalent resistance between this pin and GND should not be less than 10 k<math>\Omega</math>. The reference voltage is nominally 1.25 V.</p>

**18. Ordering Guide**

<b>Part Number</b>	<b>Package</b>	<b>Temperature</b>
Si5100-F-BC	195-BGA	-20 to 85 °C

## 19. Package Outline

Figure 15 illustrates the package details for the Si5100. Table 9 lists the values for the dimensions shown in the illustration.

**Figure 15. 195-Ball Grid Array (BGA)**

**Table 9. Package Diagram Dimensions (mm)**

Dimension	Description	Millimeters		
		Min	Nom	Max
A	Total Package Height	2.75	2.90	3.05
A1	Standoff	0.65	0.70	0.75
A2	Body Thickness	1.30	1.40	1.50
b	Solder Ball Diameter	0.65	0.70	0.75
D	Body Size	15.00 BSC		
D1	Total Array Pitch	13.00 BSC		
e	Solder Ball Pitch	1.00 BSC		
L	Die Size	3.10	3.18	3.25
p	Die Offset	2.53 BSC		
S	Pitch to Centerline	0.50 BSC		

## 20. 15x15 mm 195L CBGA Recommended PCB Layout

Symbol	Parameter	Dimension			Notes
		Min	Nom	Max	
C	Column Width	—	13.00 REF	—	
D	Row Height	—	13.00 REF	—	
E	Pad Pitch	—	1.00 BSC	—	
F	Placement Courtyard	16.00	—	—	1
X	Pad Diameter	0.64	0.68	0.72	2, 3

**Notes:**

1. The Placement Courtyard is the minimum keep-out area required to assure assembly clearances.
2. Pad Diameter is Copper Defined (Non-Solder Mask Defined/NSMD).
3. OSP Surface Finish Recommended
4. Controlling dimension is millimeters.
5. Land Pad Dimensions comply with IPC-SM-782 guidelines.
6. Target solder paste volume per pad is  $0.065 \text{ mm}^3 \pm 0.010 \text{ mm}^3$  (4000 mils $^3 \pm 600$  mils $^3$ ).  
Recommended stencil aperture dimensions to achieve target solder paste volume are 0.191mm thick x  $0.68 \pm 0.01$  mm diameter, with a 0.025 mm taper.
7. Recommended stencil type is chemically etched stainless steel with circularly tapered apertures.

## DOCUMENT CHANGE LIST

### Revision 0.7 to Revision 1.0

- Updated "Si5100 Detailed Block Diagram" on page 4 to clarify control of RXAMPMON and CMU timing source.
- Figure 1 on page 5
  - Clarified the measurement of  $V_{ICM}$ ,  $V_{OCM}$  and  $V_I$ .
- Updated Table 3 on page 8.
- Updated Table 4 on page 9.
- Updated Table 5 on page 10.
- Updated Table 6 on page 11.
- Updated Table 7 on page 12.
- Updated dimension L in Table 9 on page 36.
- Updated "Functional Description" on page 14.
  - Clarified frequency range, enabling RXAMPMON, and equations for  $V_{LOS}$ .
- Updated "Clock and Data Recovery (CDR)" on page 15.
  - Clarified slice and phase adjustment equations.
- Added Figure 4 on page 16.
- Corrected Figure 5 on page 17.
- Added Figure 11 on page 23.
- Added Figure 12 on page 23.

### Revision 1.0 to Revision 1.1

- Updated Table 2 on page 6.
- Updated Figures 11 and 12 on page 23.
- Updated Table 9, "Package Diagram Dimensions (mm)," on page 36.

**NOTES:**
