

# Multiple Switch Detection Interface

The 33993 Multiple Switch Detection Interface is designed to detect the closing and opening of up to 22 switch contacts. The switch status, either open or closed, is transferred to the microprocessor unit (MCU) through a serial peripheral interface (SPI). The device also features a 22-to-1 analog multiplexer for reading inputs as analog. The analog input signal is buffered and provided on the AMUX output pin for the MCU to read.

The 33993 device has two modes of operation, Sleep and Normal. The Sleep mode provides low quiescent current and enables the wake-up features of the device. Normal mode allows programming of the device and supplies switch contacts with pull-up or pull-down current as it monitors switch change of state.

The 33993 is packaged in the 32-pin wide-body SOIC, reducing circuit board area. Low quiescent current makes the 33993 ideal for automotive and industrial products requiring low sleep state currents.

### Features

- Designed to Operate  $5.5\text{ V} \leq V_{PWR} \leq 26\text{ V}$
- Switch Input Voltage Range  $-14\text{ V}$  to  $V_{PWR}$ , 40 V Max
- Interfaces Directly to Microprocessor Using 3.3 V/5.0 V SPI Protocol
- Selectable Wake-Up on Change of State
- Selectable Wetting Current (16 mA or 2.0 mA)
- 8 Programmable Inputs (Switches to Battery or Ground)
- 14 Switch-to-Ground Inputs
- $V_{PWR}$  Standby Current 100  $\mu\text{A}$  Typical,  $V_{DD}$  Standby Current 20  $\mu\text{A}$  Typical
- Active Interrupt ( $\overline{\text{INT}}$ ) on Change-of-Switch State
- Pb-Free Packaging Designated by Suffix Code EW

## PIN CONNECTIONS

Figure 3. 33993 Pin Connections

Table 1. 33993 Pin Definitions

A functional description of each pin can be found in the Functional Pin Description section beginning on [page 9](#).

Pin Number	Pin Name	Formal Name	Definition
1	GND	Ground	Ground for logic, analog, and switch to battery inputs.
2	SI	SPI Slave In	SPI control data input pin from MCU to the 33993.
3	SCLK	Serial Clock	SPI control clock input pin.
4	$\overline{\text{CS}}$	Chip Select	SPI control chip select input pin from MCU to the 33993. Logic 0 allows data to be transferred in.
5–8 25–28	SP0–3 SP4–7	Programmable Switches 0–7	Programmable switch-to-battery or switch-to-ground input pins.
9–15, 18–24	SG0–6, SG13–7	Switch-to-Ground Inputs 0–13	Switch-to-ground input pins.
16	$V_{\text{PWR}}$	Battery Input	Battery supply input pin. Pin requires external reverse battery protection.
17	$\overline{\text{WAKE}}$	Wake-Up	Open drain wake-up output. Designed to control a power supply enable pin.
29	$\overline{\text{INT}}$	Interrupt	Open-drain output to the MCU. Used to indicate an input switch change of state.
30	AMUX	Analog Multiplex Output	Analog multiplex output.
31	$V_{\text{DD}}$	Voltage Drain Supply	3.3/5.0 V supply. Sets SPI communication level for the SO driver.
32	SO	SPI Slave Out	Provides digital data from 33993 to the MCU.

## ELECTRICAL CHARACTERISTICS

### MAXIMUM RATINGS

**Table 2. Maximum Ratings**

All voltages are with respect to ground unless otherwise noted. Exceeding these ratings may cause a malfunction or permanent damage to the device.

Ratings	Symbol	Value	Unit
<b>ELECTRICAL RATINGS</b>			
V <sub>DD</sub> Supply Voltage	–	-0.3 to 7.0	V <sub>DC</sub>
$\overline{CS}$ , SI, SO, SCLK, $\overline{INT}$ , AMUX <sup>(1)</sup>	–	-0.3 to 7.0	V <sub>DC</sub>
$\overline{WAKE}$ <sup>(1)</sup>	–	-0.3 to 40	V <sub>DC</sub>
V <sub>PWR</sub> Supply Voltage <sup>(1)</sup>	–	-0.3 to 50	V <sub>DC</sub>
Switch Input Voltage Range	–	-14 to 40	V <sub>DC</sub>
Frequency of SPI Operation (V <sub>DD</sub> = 5.0 V)	–	6.0	MHz
ESD Voltage <sup>(2)</sup>			V
Human Body Model	V <sub>ESD1</sub>	±4000	
Machine Model	V <sub>ESD2</sub>	±200	
<b>THERMAL RATINGS</b>			
Storage Temperature	T <sub>STG</sub>	-55 to 150	°C
Operating Case Temperature	T <sub>C</sub>	-40 to 125	°C
Operating Junction Temperature	T <sub>J</sub>	-40 to 150	°C
<b>THERMAL RESISTANCE</b>			
Power Dissipation (T <sub>A</sub> = 25°C) <sup>(3)</sup>	P <sub>D</sub>	1.7	W
Thermal Resistance			°C/W
Junction to Ambient	R <sub>θJA</sub>	74	
Junction to Lead	R <sub>θJL</sub>	25	
Peak Package Reflow Temperature During Reflow <sup>(4), (5)</sup>	T <sub>PPRT</sub>	Note 5	°C

**Notes**

1. Exceeding these limits may cause malfunction or permanent damage to the device.
2. ESD testing is performed in accordance with the Human Body Model (HBM) (C<sub>ZAP</sub> = 100 pF, R<sub>ZAP</sub> = 1500 Ω), the Machine Model (MM) (C<sub>ZAP</sub> = 200 pF, R<sub>ZAP</sub> = 0 Ω), and the Charge Device Model (CDM), Robotic (C<sub>ZAP</sub> = 4.0pF).
3. Maximum power dissipation at T<sub>J</sub> = 150°C junction temperature with no heat sink used.
4. Pin soldering temperature limit is for 10 seconds maximum duration. Not designed for immersion soldering. Exceeding these limits may cause malfunction or permanent damage to the device.
5. Freescale's Package Reflow capability meets Pb-free requirements for JEDEC standard J-STD-020C. For Peak Package Reflow Temperature and Moisture Sensitivity Levels (MSL), Go to [www.freescale.com](http://www.freescale.com), search by part number [e.g. remove prefixes/suffixes and enter the core ID to view all orderable parts. (i.e. MC33xxx enter 33xxx), and review parametrics.

**STATIC ELECTRICAL CHARACTERISTICS**

**Table 3. Static Electrical Characteristics**

Characteristics noted under conditions  $3.1\text{ V} \leq V_{DD} \leq 5.25\text{ V}$ ,  $8.0\text{ V} \leq V_{PWR} \leq 16\text{ V}$ ,  $-40^\circ\text{C} \leq T_C \leq 125^\circ\text{C}$ , unless otherwise noted. Typical values noted reflect the approximate parameter means  $V_{PWR} = 13\text{ V}$ ,  $T_A = 25^\circ\text{C}$  under nominal conditions unless otherwise noted.

Characteristic	Symbol	Min	Typ	Max	Unit
<b>POWER INPUT</b>					
Supply Voltage					V
Supply Voltage Range Quasi-Functional <sup>(6)</sup>	$V_{PWR(QF)}$	5.5	–	8.0	
Fully Operational	$V_{PWR(FO)}$	8.0	–	26	
Supply Voltage Range Quasi-Functional <sup>(6)</sup>	$V_{PWR(QF)}$	26	–	40	
Supply Current					mA
All Switches Open, Normal Mode, Tri-State Disabled	$I_{PWR(ON)}$	–	2.0	4.0	
Sleep State Supply Current					$\mu\text{A}$
Scan Timer = 64 ms, Switches Open	$I_{PWR(SS)}$	40	70	100	
Logic Supply Voltage	$V_{DD}$	3.1	–	5.25	V
Logic Supply Current					mA
All Switches Open, Normal Mode	$I_{DD}$	–	0.25	0.5

Scan Timer = 64 ms, Switches Open	$I_{DD(SS)}$	–	10	20	
<b>SWITCH INPUT</b>					
Pulse Wetting Current Switch-to-Battery (Current Sink)	$I_{PULSE}$	12	15	18	mA
Pulse Wetting Current Switch-to-Ground (Current Source)	$I_{PULSE}$	12	16	18	mA
Sustain Current Switch-to-Battery Input (Current Sink)	$I_{SUSTAIN}$	1.8	2.0	2.2	mA
Sustain Current Switch-to-Ground Input (Current Source)	$I_{SUSTAIN}$	1.8	2.0	2.2	mA
Sustain Current Matching Between Channels on Switch-to-Ground Inputs					%
	$\frac{I_{SUS(MAX)} - I_{SUS(MIN)}}{I_{SUS(MIN)}} \times 100$	–	2.0	4.0	
Input Offset Current when Selected as Analog	$I_{OFFSET}$	-2.0	1.4	2.0	$\mu\text{A}$
Input Offset Voltage when Selected as Analog					mV
$V_{(SP\&SGINPUTS)}$ to AMUX Output	$V_{OFFSET}$	-10	2.5	10	
Analog Operational Amplifier Output Voltage					mV
Sink 250 $\mu\text{A}$	$V_{OL}$	–	10	30	
Analog Operational Amplifier Output Voltage					V
Source 250 $\mu\text{A}$	$V_{OH}$	$V_{DD} - 0.1$	–	–	
Switch Detection Threshold	$V_{TH}$	3.70	4.0	4.3	V
Switch Input Voltage Range	$V_{IN}$	-14	–	40	V
Temperature Monitor <sup>(7), (8)</sup>	$T_{LIM}$	155	–	185	$^\circ\text{C}$
Temperature Monitor Hysteresis <sup>(8)</sup>	$T_{LIM(HYS)}$	5.0	10	15	$^\circ\text{C}$

Notes

- Device operational. Table parameters may be out of specification.
- Thermal shutdown of 16 mA pull-up and pull-down current sources only. 2.0 mA current source/sink and all other functions remain active.
- This parameter is guaranteed by design but is not production tested.

**Table 3. Static Electrical Characteristics (continued)**

Characteristics noted under conditions  $3.1\text{ V} \leq V_{DD} \leq 5.25\text{ V}$ ,  $8.0\text{ V} \leq V_{PWR} \leq 16\text{ V}$ ,  $-40^\circ\text{C} \leq T_C \leq 125^\circ\text{C}$ , unless otherwise noted. Typical values noted reflect the approximate parameter means  $V_{PWR} = 13\text{ V}$ ,  $T_A = 25^\circ\text{C}$  under nominal conditions unless otherwise noted.

Characteristic	Symbol	Min	Typ	Max	Unit
<b>DIGITAL INTERFACE</b>

SI, $\overline{CS}$ , SCLK Signal Fall Time <sup>(13)</sup>	$t_{F(SI)}$	–	5.0	–	ns
Time from Falling Edge of $\overline{CS}$ to SO Low Impedance <sup>(14)</sup>	$t_{SO(EN)}$	–	–	55	ns
Time from Rising Edge of $\overline{CS}$ to SO High Impedance <sup>(15)</sup>	$t_{SO(DIS)}$	–	–	55	ns
Time from Rising Edge of SCLK to SO Data Valid <sup>(16)</sup>	$t_{VALID}$	–	25	55	ns

## Notes

- These parameters are guaranteed by design. Production test equipment uses a 4.16 MHz, 5.0 V SPI interface.
- This parameter is guaranteed by design but not production tested.
- Rise and Fall time of the incoming SI,  $\overline{CS}$ , and SCLK signals are suggested for design considerations to prevent the occurrence of double pulsing.
- Time required for valid output status data to be available on SO pin.
- Time required for output states data to be terminated at SO pin.
- Time required to obtain valid data out from SO following the rise of SCLK with 200 pF load.

Figure 6. Normal Mode Interrupt Operation

## FUNCTIONAL DESCRIPTION

### INTRODUCTION

The 33993 device is an integrated circuit designed to provide systems with ultra-low quiescent sleep/wake-up modes and a robust interface between switch contacts and a microprocessor. The 33993 replaces many of the discrete components required when interfacing to microprocessor-based systems while providing switch ground offset protection, contact wetting current, and system wake-up.

The 33993 features 8-programmable switch-to-ground or switch-to-battery inputs and 14 switch-to-ground inputs. All

switch inputs may be read as analog inputs through the analog multiplexer (AMUX). Other features include a programmable wake-up timer, programmable interrupt timer, programmable wake-up/interrupt bits, and programmable wetting current settings.

This device is designed primarily for automotive applications but may be used in a variety of other applications such as computer, telecommunications, and industrial controls.

### FUNCTIONAL PIN DESCRIPTION

#### CHIP SELECT ( $\overline{CS}$ )

The system MCU selects the 33993 to receive communication using the chip select ( $\overline{CS}$ ) pin. With the  $\overline{CS}$  in a logic low state, command words may be sent to the 33993 via the serial input (SI) pin, and switch status information can be received by the MCU via the serial output (SO) pin. The falling edge of  $\overline{CS}$  enables the SO output, latches the state of the  $\overline{INT}$  pin, and the state of the external switch inputs.

Rising edge of the  $\overline{CS}$  initiates the following operation:

1. Disables the SO driver (high impedance)
2.  $\overline{INT}$  pin is reset to logic [1], except when additional switch changes occur during  $\overline{CS}$  low. (See [Figure 6](#).)

Activates the received command word, allowing the 33993 to act upon new data from switch inputs.

To avoid any spurious data, it is essential the high-to-low and low-to-high transitions of the  $\overline{CS}$  signal occur only when SCLK is in a logic low state. A clean  $\overline{CS}$  signal is needed to ensure no incomplete SPI words are sent to the device. Internal to the 33993 device is an active pull-up to  $V_{DD}$  on the  $\overline{CS}$ .

In Sleep mode the negative edge of the  $\overline{CS}$  ( $V_{DD}$  applied) will wake up the 33993 device. Data received from the device during  $\overline{CS}$  wake-up may not be accurate.

#### SERIAL CLOCK (SCLK)

The system clock (SCLK) pin clocks the internal shift register of the 33993. The SI data is latched into the input shift register on the falling edge of SCLK signal. The SO pin shifts the switch status bits out on the rising edge of SCLK. The SO data is available for the MCU to read on the falling edge of SCLK. False clocking of the shift register must be avoided to ensure validity of data. It is essential the SCLK pin be in a logic low state whenever  $\overline{CS}$  makes any transition. For this reason, it is recommended, though not necessary, that the SCLK pin is commanded to a low logic state as long as the device is not accessed and  $\overline{CS}$  is in a logic high state. When the  $\overline{CS}$  is in a logic high state, any signal on the SCLK and SI pins will be ignored and the SO pin is tri-state.

#### SPI SLAVE IN (SI)

The SI pin is used for serial instruction data input. SI information is latched into the input register on the falling edge of SCLK. A logic high state present on SI will program a *one* in the command word on the rising edge of the  $\overline{CS}$  signal. To program a complete word, 24 bits of information must be entered into the device.

#### SPI SLAVE OUT (SO)

The SO pin is the output from the shift register. The SO pin remains tri-stated until the  $\overline{CS}$  pin transitions to a logic low state. All *open switches* are reported as *zero*, all *closed switches* are reported as *one*. The negative transition of  $\overline{CS}$  enables the SO driver.

The first positive transition of SCLK will make the status data bit 24 available on the SO pin. Each successive positive clock will make the next status data bit available for the MCU to read on the falling edge of SCLK. The SI/SO shifting of the data follows a first-in-first-out protocol, with both input and output words transferring the most significant bit (MSB) first.

#### INTERRUPT ( $\overline{INT}$ )

The  $\overline{INT}$  pin is an interrupt output from the 33993 device. The  $\overline{INT}$  pin is an open-drain output with an internal pull-up to  $V_{DD}$ . In Normal mode, a switch state change will trigger the  $\overline{INT}$  pin (when enabled). The  $\overline{INT}$  pin and  $\overline{INT}$  bit in the SPI register are latched on the falling edge of  $\overline{CS}$ . This permits the MCU to determine the origin of the interrupt. When two 33993 devices are used, only the device initiating the interrupt will have the  $\overline{INT}$  bit set. The  $\overline{INT}$  pin is cleared on the rising edge of  $\overline{CS}$ . The  $\overline{INT}$  pin will not clear with rising edge of  $\overline{CS}$  if a switch contact change has occurred while  $\overline{CS}$  was low.

In a multiple 33993 device system with  $\overline{WAKE}$  high and  $V_{DD}$  on (Sleep mode), the falling edge of  $\overline{INT}$  will place all 33993s in Normal mode.

## WAKE-UP ( $\overline{\text{WAKE}}$ )

The  $\overline{\text{WAKE}}$  pin is an open-drain output and a wake-up input. The pin is designed to control a power supply Enable pin. In the Normal mode, the  $\overline{\text{WAKE}}$  pin is low. In the Sleep mode, the  $\overline{\text{WAKE}}$  pin is high. The  $\overline{\text{WAKE}}$  pin has a pull-up to the internal +5.0 V supply.

In Sleep mode with the  $\overline{\text{WAKE}}$  pin high, falling edge of  $\overline{\text{WAKE}}$  will place the 33993 in Normal mode. In Sleep mode with  $V_{\text{DD}}$  applied, the  $\overline{\text{INT}}$  pin must be high for negative edge of  $\overline{\text{WAKE}}$  to wake up the device. If  $V_{\text{DD}}$  is not applied to the device in Sleep mode,  $\overline{\text{INT}}$  does not affect the  $\overline{\text{WAKE}}$  operation.

## BATTERY INPUT ( $V_{\text{PWR}}$ )

The  $V_{\text{PWR}}$  pin is battery input and Power-ON Reset to the 33993 IC. The  $V_{\text{PWR}}$  pin requires external reverse battery and transient protection. Maximum input voltage on  $V_{\text{PWR}}$  is 50 V. All wetting, sustain, and internal logic current is provided from the  $V_{\text{PWR}}$  pin.

## VOLTAGE DRAIN SUPPLY ( $V_{\text{DD}}$ )

The  $V_{\text{DD}}$  input pin is used to determine logic levels on the microprocessor interface (SPI) pins. Current from  $V_{\text{DD}}$  is used to drive SO output and the pull-up current for  $\overline{\text{CS}}$  and  $\overline{\text{INT}}$  pins.  $V_{\text{DD}}$  must be applied for wake-up from negative edge of  $\overline{\text{CS}}$  or  $\overline{\text{INT}}$ .

## GROUND (GND)

The GND pin provides ground for the IC as well as ground for inputs programmed as switch-to-battery inputs.

## PROGRAMMABLE SWITCHES 0–7 ( $\text{SP0–SP7}$ )

The 33993 device has 8 switch inputs capable of being programmed to read switch-to-ground or switch-to-battery contacts. The input is compared with a 4.0 V reference. When programmed to be switch-to-battery, voltages greater than 4.0 V are considered closed. Voltages less than 4.0 V are considered open. The opposite holds true when inputs are programmed as switch-to-ground. Programming features are defined in [Table 5](#) through [Table 10](#) in the [Logic Commands and Registers](#) section of this datasheet. Voltages greater than the  $V_{\text{PWR}}$  supply voltage will source current through the SP inputs to the  $V_{\text{PWR}}$  pin. Transient battery voltages greater than 40 V must be clamped by an external device.

## SWITCH-TO-GROUND INPUTS 0–13 ( $\text{SG0–SG13}$ )

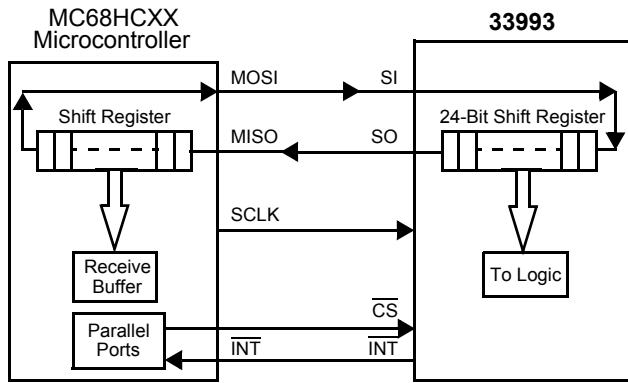

The SGn pins are switch-to-ground inputs only. The input is compared with a 4.0 V reference. Voltages greater than 4.0 V are considered open. Voltages less than 4.0 V are considered closed. Programming features are defined in [Table 5](#) through [Table 10](#) in the [Logic Commands and Registers](#) section of this datasheet. Voltages greater than the  $V_{\text{PWR}}$  supply voltage will source current through the SG inputs to the  $V_{\text{PWR}}$  pin. Transient battery voltages greater than 40 V must be clamped by an external device.

## FUNCTIONAL DEVICE OPERATION

### MCU INTERFACE DESCRIPTION

The 33993 device directly interfaces to a 3.3 V or 5.0 V microcontroller unit (MCU). SPI serial clock frequencies up to 6.0 MHz may be used for programming and reading switch input status (production tested at 4.16 MHz). [Figure 7](#) illustrates the configuration between an MCU and one 33993.

Serial peripheral interface (SPI) data is sent to the 33993 device through the SI input pin. As data is being clocked into the SI pin, status information is being clocked out of the device by the SO output pin. The response to a SPI command will always return the switch status, interrupt flag, and thermal flag. Input switch states are latched into the SO register on the falling edge of the chip select ( $\overline{CS}$ ) pin. Twenty-four bits are required to complete a transfer of information between the 33993 and the MCU.

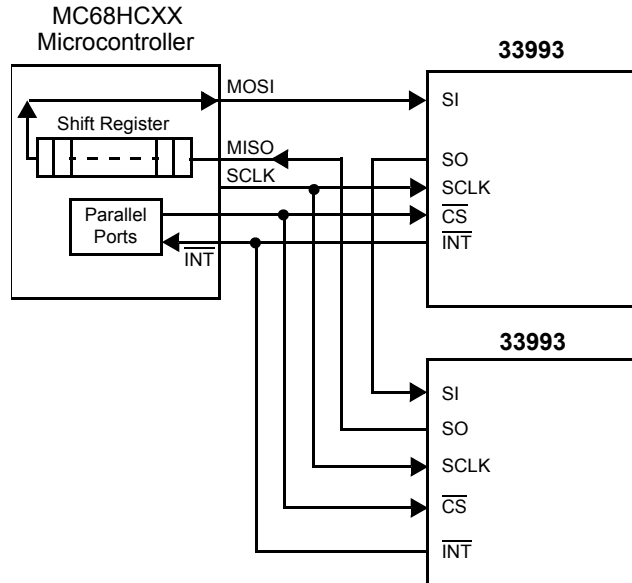

**Figure 7. SPI Interface with Microprocessor**

Two or more 33993 devices may be used in a module system. Multiple ICs may be SPI-configured in parallel or serial. [Figures 8](#) and [9](#) show the configurations. When using the serial configuration, 48-clock cycles are required to transfer data in/out of the ICs.

**Figure 8. SPI Parallel Interface with Microprocessor**

**Figure 9. SPI Serial Interface with Microprocessor**

## OPERATIONAL MODES

### POWER SUPPLY

The 33993 is designed to operate from 5.5 V to 40 V on the VPWR pin. Characteristics are provided from 8.0 V to 16 V for the device. Switch contact currents and the internal logic supply are generated from the VPWR pin. The VDD supply pin is used to set the SPI communication voltage levels, current source for the SO driver, and pull-up current on INT and CS.

The VDD supply may be removed from the device to reduce quiescent current. If VDD is removed while the device is in Normal mode, the device will remain in Normal mode. If VDD is removed in Sleep mode, the device will remain in Sleep mode until wake-up input is received (WAKE high to low, switch input or interrupt timer expires).

Removing VDD from the device disables SPI communication and will not allow the device to wake up from INT and CS pins.

### POWER-ON RESET (POR)

Applying VPWR to the device will cause a Power-ON Reset and place the device in Normal mode.

Default settings from Power-ON Reset via VPWR or Reset Command are as follows:

- Programmable Switch – Set to Switch to Battery
- All Inputs Set as Wake-Up
- Wetting Current On (16 mA)
- Wetting Current Timer On (20 ms)
- All Inputs Tri-State
- Analog Select 00000 (No Input Channel Selected)

### MODES OF OPERATION

The 33993 has two operating modes, Normal mode and Sleep mode. A discussion on Normal mode begins below. A discussion on Sleep mode begins on page 17.

### NORMAL MODE

Normal mode may be entered by the following events:

- Application of VPWR to the IC
- Change-of-Switch State (when enabled)
- Falling Edge of WAKE
- Falling Edge of INT (with VDD = 5.0 V and WAKE at Logic [1])
- Falling Edge of CS (with VDD = 5.0 V)
- Interrupt Timer Expires

Only in Normal mode with VDD applied can the registers of the 33993 be programmed through the SPI.

The registers that may be programmed in Normal mode are listed below. Further explanation of each register is provided in subsequent paragraphs.

- [Programmable Switch Register](#) (*Settings Command*)
- [Wake-Up/Interrupt Register](#) (*Wake-Up/Interrupt Command*)
- [Wetting Current Register](#) (*Metallic Command*)
- [Wetting Current Timer Register](#) (*Wetting Current Timer Enable Command*)
- [Tri-State Register](#) (*Tri-State Command*)
- [Analog Select Register](#) (*Analog Command*)
- [Calibration of Timers](#) (*Calibration Command*)
- [Reset](#) (*Reset Command*)

Figure 6 is a graphical description of the device operation in Normal mode. Switch states are latched into the input register on the falling edge of CS. The INT to the MCU is cleared on the rising edge of CS. However, INT will not clear on rising edge of CS if a switch has closed during SPI communication (CS low). This prevents switch states from being missed by the MCU.

## LOGIC COMMANDS AND REGISTERS

### PROGRAMMABLE SWITCH REGISTER

Inputs SP0 to SP7 may be programmable for switch-to-battery or switch-to-ground. These inputs types are defined using the *settings command* (refer to [Table 5](#)). To set an SPn input for switch-to-battery, a logic [1] for the appropriate bit must be set. To set an SPn input for switch-to-ground, a logic [0] for the appropriate bit must be set. The MCU may change

or update the Programmable Switch Register via software at any time in Normal mode. Regardless of the setting, when the SPn input switch is closed a logic [1] will be placed in the Serial Output Response Register (refer to [Table 16](#), page [17](#)).

**Table 5. Settings Command**

Settings Command								Not used								Battery/Ground Select							
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	1	X	X	X	X	X	X	X	X	sp7	sp6	sp5	sp4	sp3	sp2	sp1	sp0

### WAKE-UP/INTERRUPT REGISTER

The Wake-Up/Interrupt Register defines the inputs that are allowed to wake the 33993 from Sleep mode or set the INT pin low in Normal mode. Programming the wake-up/interrupt bit to logic [0] will disable the specific input from generating an interrupt and will disable the specific input from

waking the IC in Sleep mode (refer to [Table 6](#)). Programming the wake-up/interrupt bit to logic [1] will enable the specific input to generate an interrupt with switch change of state and will enable the specific input as wake-up. The MCU may change or update the Wake-Up/Interrupt Register via software at any time in Normal mode.

**Table 6. Wake-Up/Interrupt Command**

Wake-Up/Interrupt Command								Command Bits															
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	0	0	0	0	0	1	1	X	X	sg1 3	sg1 2	sg1 1	sg1 0	sg9	sg8	sg7	sg6	sg5	sg4	sg3	sg2	sg1	sg0

### WETTING CURRENT REGISTER

The 33993 has two levels of switch contact current, 16 mA and 2.0 mA (see [Figure 10](#)). The *metallic command* is used to set the switch contact current level (refer to [Table 7](#)). Programming the metallic bit to logic [0] will set the switch wetting current to 2.0 mA. Programming the metallic bit to logic [1] will set the switch contact wetting current to 16 mA. The MCU may change or update the Wetting Current Register via software at any time in Normal mode.

Wetting current is designed to provide higher levels of current during switch closure. The higher level of current is designed to keep switch contacts from building up oxides that form on the switch contact surface.

**Figure 10. Contact Wetting and Sustain Current**

**Table 7. Metallic Command**

Metallic Command								Command Bits															
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	0	0	X	X	X	X	X	X	X	X	sp7	sp6	sp5	sp4	sp3	sp2	sp1	sp0
0	0	0	0	0	1	0	1	X	X	sg1 3	sg1 2	sg1 1	sg1 0	sg9	sg8	sg7	sg6	sg5	sg4	sg3	sg2	sg1	sg0

**WETTING CURRENT TIMER REGISTER**

Each switch input has a designated 20 ms timer. The timer starts when the specific switch input crosses the comparator threshold (4.0 V). When the 20 ms timer expires, the contact current is reduced from 16 mA to 2.0 mA. The wetting current timer may be disabled for a specific input. When the timer is disabled, 16 mA of current will continue to flow through the

closed switch contact. With multiple wetting current timers disabled, power dissipation for the IC must be considered.

The MCU may change or update the Wetting Current Timer Register via software at any time in Normal mode. This allows the MCU to control the amount of time wetting current is applied to the switch contact. Programming the wetting current timer bit to logic [0] will disable the wetting current timer. Programming the wetting current timer bit to logic [1] will enable the wetting current timer (refer to [Table 8](#)).

**Table 8. Wetting Current Timer Enable Command**

Wetting Current Timer Commands								Command Bits															
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	X	X	X	X	X	X	X	X	sp7	sp6	sp5	sp4	sp3	sp2	sp1	sp0

**TRI-STATE REGISTER**

The *tri-state command* is used to set the SPn or SGn input node as high impedance (refer to [Table 9](#)). By setting the Tri-State Register bit to logic [1], the input will be high impedance regardless of the metallic command setting. The

comparator on each input remains active. This command allows the use of each input as a comparator with a 4.0 V threshold. The MCU may change or update the Tri-State Register via software at any time in Normal mode.

**Table 9. Tri-State Command**

Tri-State Commands								Command Bits															
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	0	0	1	X	X	X	X	X	X	X	X	sp7	sp6	sp5	sp4	sp3	sp2	sp1	sp0
0	0	0	0	1	0	1	0	X	X	sg1 3	sg1 2	sg1 1	sg1 0	sg9	sg8	sg7	sg6	sg5	sg4	sg3	sg2	sg1	sg0

**ANALOG SELECT REGISTER**

The analog voltage on switch inputs may be read by the MCU using the *analog command* (refer to [Table 10](#)). Internal to the IC is a 22-to-1 analog multiplexer. The voltage present on the selected input pin is buffered and made available on the AMUX output pin. The AMUX output pin is clamped to a maximum of V<sub>DD</sub> volts regardless of the higher voltages present on the input pin. After an input has been selected as the analog, the corresponding bit in the next SO data stream will be logic [0]. When selecting a channel to be read as analog, the user must also set the desired current (16 mA, 2.0 mA, or high impedance). Setting bit 6 and bit 5 to 0,0

selects the input as high impedance. Setting bit 6 and bit 5 to 0,1 selects 2.0 mA, and 1,0 selects 16 mA. Setting bit 6 and bit 5 to 1,1 in the Analog Select Register is not allowed and will place the input as an analog input with high impedance.

Analog currents set by the *analog command* are pull-up currents for all SGn and SPn inputs (refer to [Table 10](#)). The *analog command* does not allow pull-down currents on the SPn inputs. Setting the current to 16 mA or 2.0 mA may be useful for reading sensor inputs. Further information is provided in the [Typical Applications](#) section of this datasheet beginning on page [20](#). The MCU may change or update the

Analog Select Register via software at any time in Normal mode.

**Table 10. Analog Command**

Analog Command								Not used									Current Select		Analog Channel Select

**CALIBRATION OF TIMERS**

In cases where an accurate time base is required, the user may calibrate the internal timers using the *calibration command* (refer to [Table 12](#)). After the 33993 device receives the calibration command, the device expects 512  $\mu$ s logic [0] calibration pulse on the  $\overline{CS}$  pin. The pulse is used to calibrate the internal clock. No other SPI pins should transition during this 512  $\mu$ s calibration pulse. Because the oscillator frequency changes with temperature, calibration is required for an accurate time base. Calibrating the timers has no affect on the quiescent current measurement. The calibration command simply makes the time base more accurate. The *calibration command* may be used to update the device on a periodic basis.

**Table 12. Calibration Command**

Calibration Command								Command Bits															
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**RESET**

The reset command resets all registers to Power-ON Reset (POR) state. Refer to [Table 14](#), page 16, for POR

states or the paragraph entitled [Power-ON Reset \(POR\)](#) on page 12 of this datasheet.

**Table 13. Reset Command**

**EXAMPLE OF NORMAL MODE OPERATION**

The operation of the device in Normal Mode is defined by the states of the programmable internal control registers. A typical application may have the following settings:

- Programmable Switch – Set to Switch-to-Ground
- All Inputs Set as Wake-Up
- Wetting Current On (16 mA)
- Wetting Current Timer On (20 ms)
- All inputs Tri-State-Disabled (comparator is active)
- Analog select 00000 (no input channel selected)

With the device programmed as above, an interrupt will be generated with each switch contact change of state (open-to-close or close-to-open) and 16 mA of contact wetting current will be source for 20 ms. The INT pin will remain low until switch status is acknowledged by the microprocessor. It is critical to understand INT will not be cleared on the rising edge of CS if a switch closure occurs while CS is low. The maximum duration a switch state change can exist without acknowledgement depends on the software response time to the interrupt. Figure 4, page 8, shows the interaction between changing input states and the INT and CS pins.

If desired the user may disable interrupts (wake up/interrupt command) from the 33993 device and read the switch states on a periodic basis. Switch activation and deactivation faster than the MCU read rate will not be acknowledged.

The 33993 device will exit the Normal mode and enter the Sleep mode only with a valid sleep command.

**SLEEP MODE**

Sleep mode is used to reduce system quiescent currents. Sleep mode may be entered only by sending the sleep command. All register settings programmed in Normal mode will be maintained in Sleep mode.

The 33993 will exit Sleep mode and enter Normal mode when any of the following events occur:

- Input Switch Change of State (when enabled)
- Interrupt Timer Expire
- Falling Edge of WAKE
- Falling Edge of INT (with VDD = 5.0 V and WAKE at Logic [1])
- Falling Edge of CS (with VDD = 5.0 V)
- Power-ON Reset (POR)

The VDD supply may be removed from the device during Sleep mode. However removing VDD from the device in Sleep mode will disable a wake-up from falling edge of INT and CS.

**Note** In cases where CS is used to wake the device, the first SO data message is not valid.

The sleep command contains settings for two programmable timers for Sleep mode, the interrupt timer and the scan timer, as shown in Table 17.

The interrupt timer is used as a periodic wake-up timer. When the timer expires, an interrupt is generated and the device enters Normal mode. Table 18 shows the programmable settings of the Interrupt timer.

**Table 17. Sleep Command**

Sleep Command								Command Bits															
23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	1	0	0	X	X	X	X	X	X	X	X	X	X	int timer	int timer	int timer	scan timer	scan timer	scan timer

**Table 18. Interrupt Timer**

Bits 543	Interrupt Period
000	32 ms
001	64 ms
010	128 ms
011	256 ms
100	512 ms
101	1.024 s
110	2.048 s
111	4.096 s

The scan timer sets the polling period between input switch reads in Sleep mode. The period is set in the *sleep command* and may be set to 000 (no period) to 111 (64 ms). In Sleep mode when the scan timer expires, inputs will behave as programmed prior to sleep command. The 33993 will wake up for approximately 125 μs and read the switch inputs. At the end of the 125 μs, the input switch states are compared with the switch state prior to sleep command. When switch state changes are detected, an interrupt (when enabled; refer to *wake-up/interrupt command* description on page 13) is generated and the device enters Normal mode. Without switch state changes, the 33993 will reset the scan timer, inputs become tri-state, and the Sleep mode continues until the scan timer expires again.

Table 19 shows the programmable settings of the Scan timer.

**Table 19. Scan Timer**

Bits 210	Scan Period
000	No Scan
001	1.0 ms
010	2.0 ms
011	4.0 ms
100	8.0 ms
101	16 ms

**Table 19. Scan Timer**

Bits 210	Scan Period
110	32 ms
111	64 ms

**Note** The interrupt and scan timers are disabled in the Normal mode.

Figure 5, page 8, is a graphical description of how the 33993 device exits Sleep mode and enters Normal mode. Notice that the device will exit Sleep mode when the interrupt timer expires or when a switch change of state occurs. The falling edge of INT triggers the MCU to wake from Sleep state. Figure 11 illustrates the current consumed during Sleep mode. During the 125 μs, the device is fully active and switch states are read. The quiescent current is calculated by integrating the normal running current over scan period plus approximately 60 μA.

**Figure 11. Sleep Current Waveform**

**TEMPERATURE MONITOR**

With multiple switch inputs closed and the device programmed with the wetting current timers disabled, considerable power will be dissipated by the IC. For this reason temperature monitoring has been implemented. The temperature monitor is active in the Normal mode only. When the IC temperature is above the thermal limit, the temperature monitor will do all of the following:

- Generate an interrupt
- Force all 16 mA pull-up and pull-down current sources to revert to 2.0 mA current sources.
- Maintain the 2.0 mA current source and all other functionality
- Set the thermal flag bit in the SPI output register

The thermal flag bit in the SPI word will be cleared on rising edge of  $\overline{CS}$  provided the die temperature has cooled below the thermal limit. When die temperature has cooled below thermal limit, the device will resume previously programmed settings.

## TYPICAL APPLICATIONS

### INTRODUCTION

The 33993's primary function is the detection of open or closed switch contacts. However, there are many features that allow the device to be used in a variety of applications. The following is a list of applications to consider for the IC:

- Sensor Power Supply
- Switch Monitor for Metallic or Elastomeric Switches
- Analog Sensor Inputs (Ratiometric)
- Power MOSFET/LED Driver and Monitor
- Multiple 33993 Devices in a Module System

The following paragraphs describe the applications in detail.

### SENSOR POWER SUPPLY

Each input may be used to supply current to sensors external to a module. Many sensors such as Hall effect, pressure sensors, and temperature sensors require a supply voltage to power the sensor and provide an open collector or analog output. [Figure 12](#) shows how the 33993 may be used to supply power and interface to these types of sensors. In an application where the input makes continuous transitions, consider using the *wake-up/interrupt command* to disable the interrupt for the particular input.

Figure 12. Sensor Power Supply

### METALLIC/ELASTOMERIC SWITCH

Metallic switch contacts often develop higher contact resistance over time owing to contact corrosion. The corrosion is induced by humidity, salt, and other elements that exist in the environment. For this reason the 33993 provides two settings for contacts. When programmed for metallic switches, the device provides higher wetting current to keep switch contacts free of oxides. The higher current occurs for the first 20 ms of switch closure. Where longer duration of wetting current is desired, the user may send the *wetting current timer command* and disable the timer. Wetting current will be continuous to the closed switch. After the time period set by the MCU, the *wetting current timer command* may be sent again to enable the timer. The user must consider power dissipation on the device when disabling the timer. (Refer to the paragraph entitled [Temperature Monitor](#), page 18.)

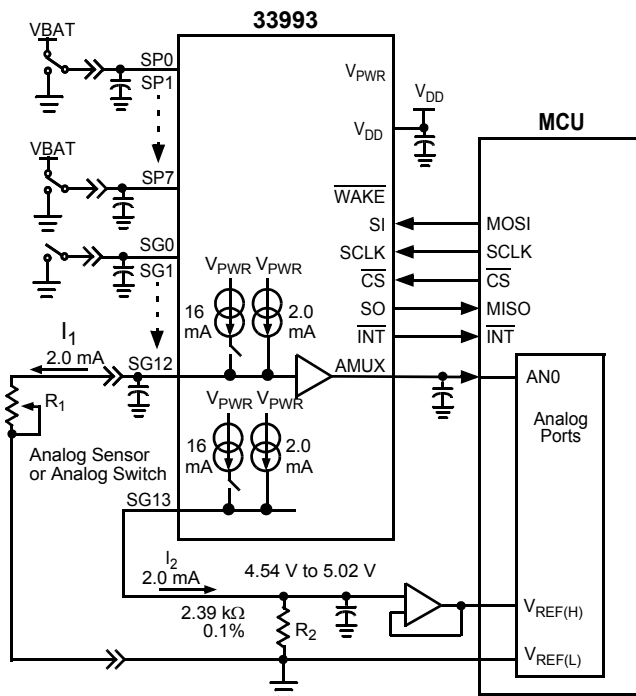

To increase the amount of wetting current for a switch contact, the user has two options. Higher wetting current to a switch may be achieved by paralleling SGn or SPn inputs. This will increase wetting current by 16 mA for each input added to the switch contact. The second option is to simply add an external resistor pull-up to the V<sub>PWR</sub> supply for switch-to-ground inputs or a resistor to ground for a switch-to-battery input. Adding an external resistor has no effect on the operation of the device.

Elastomeric switch contacts are made of carbon and have a high contact resistance. Resistance of 1.0 kΩ is common. In applications with elastomeric switches, the pull-up and pull-down currents must be reduced to prevent excessive power dissipation at the contact. Programming for a lower current settings is provided in the [Functional Device Operation](#) Section beginning on page 11 under [Table 7](#), Metallic Command.

### ANALOG SENSOR INPUTS (RATIOMETRIC)

The 33993 features a 22-to-1 analog multiplexer. Setting the binary code for a specific input in the *analog command* allows the microcontroller to perform analog to digital conversion on any of the 22 inputs. On rising edge of  $\overline{CS}$  the multiplexer connects a requested input to the AMUX pin. The AMUX pin is clamped to max of V<sub>DD</sub> volts regardless of the higher voltages present on the input pin. After an input has been selected as the analog, the corresponding bit in the next SO data stream will be logic [0].

The input pin, when selected as analog, may be configured as analog with high impedance, analog with 2.0 mA pull-up, or analog with 16 mA pull-up. [Figure 13](#), page 21, shows how the 33993 may be used to provide a ratiometric reading of variable resistive input.

**Figure 13. Analog Ratiometric Conversion**

To read a potentiometer sensor, the wiper should be grounded and brought back to the module ground, as illustrated in [Figure 13](#). With the wiper changing the impedance of the sensor, the analog voltage on the input will represent the position of the sensor.

Using the Analog feature to provide 2.0 mA of pull-up current to an analog sensor may induce error due to the accuracy of the current source. For this reason, a ratiometric conversion must be considered. Using two current sources (one for the sensor and one to set the reference voltage to the A/D converter) will yield a maximum error (owing to the 33993) of 4%.

Higher accuracy may be achieved through module level calibration. In this example, we use the resistor values from [Figure 13](#) and assume the current sources are 4% from each other. The user may use the module end-of-line tester to calculate the error in the A/D conversion. By placing a 2.0 kΩ, 0.1% resistor in the end-of-line test equipment and assuming a perfect 2.0 mA current source from the 33993, a calculated A/D conversion may be obtained. Using the equation yields the following:

$$ADC = \frac{I_1 \times R_1}{I_2 \times R_2} \times 225$$

$$ADC = \frac{2.0 \text{ mA} \times 2.0 \text{ k}\Omega}{2.0 \text{ mA} \times 2.39 \text{ k}\Omega} \times 225$$

$$ADC = 213 \text{ counts}$$

The ADC value of 213 counts is the value with 0% error (neglecting the resistor tolerance and AMUX input offset voltage). Now we can calculate the count value induced by the mismatch in current sources. From a sample device the maximum current source was measured at 2.05 mA and minimum current source was measured at 1.99 mA. This yields 3% error in A/D conversion. The A/D measurement will be as follows:

$$ADC = \frac{1.99 \text{ mA} \times 2.0 \text{ k}\Omega}{2.05 \text{ mA} \times 2.39 \text{ k}\Omega} \times 225$$

$$ADC = 207 \text{ counts}$$

This A/D conversion is 3% low in value. The error correction factor of 1.03 may be used to correct the value:

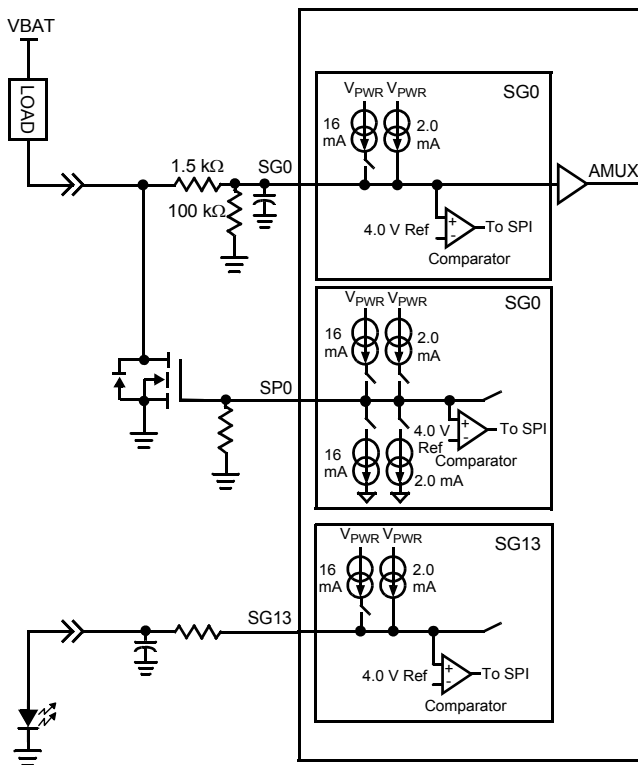

$$ADC = 207 \text{ counts} \times 1.03$$

$$ADC = 213 \text{ counts}$$

An error correction factor may then be stored in E<sup>2</sup> memory and used in the A/D calculation for the specific input. Each input used as analog measurement will have a dedicated calibrated error correction factor.

## POWER MOSFET/LED DRIVER AND MONITOR

Because of the flexible programming of the 33993 device, it may be used to drive small loads like LEDs or MOSFET gates. It was specifically designed to power up in the Normal mode with the inputs tri-state. This was done to ensure the LEDs or MOSFETs connected to the 33993 power up in the off-state. The Switch Programmable (SP0–SP7) inputs have a source-and-sink capability, providing effective MOSFET gate control. To complete the circuit, a pull-down resistor should be used to keep the gate from floating during the Sleep modes. [Figure 14](#), page 22, shows an application where the SG0 input is used to monitor the drain-to-source voltage of the external MOSFET. The 1.5 kΩ resistor is used to set the drain-to-source trip voltage. With the 2.0 mA current source enabled, an interrupt will be generated when the drain-to-source voltage is approximately 1.0 V.

**Figure 14. MOSFET or LED Driver Output**

The sequence of commands (from Normal mode with inputs tri-state) required to set up the device to drive a MOSFET are as follows:

- *wetting current timer enable command* –Disable SPn wetting current timer (refer to [Table 8](#), page 14)
- *metallic command* –Set SPn to 16 mA or 2.0 mA gate drive current (refer to [Table 7](#), page 14)
- *settings command* –Set SPn as switch-to-battery (refer to [Table 5](#), page 13)
- *tri-state command* –Disable tri-state for SPn (refer to [Table 9](#), page 14)

After the *tri-state command* has been sent (tri-state disable), the MOSFET gate will be pulled to ground. From this point forward the MOSFET may be turned on and off by sending the *settings command*:

- *settings command* –SPn as switch-to-ground (MOSFET ON)
- *settings command* –SPn as switch-to-battery (MOSFET OFF)

Monitoring of the MOSFET drain in the OFF state provides open load detection. This is done by using an SGn input comparator. With the SGn input in tri-state, the load will pull up the SGn input to battery. With open load the SGn pin is pulled down to ground through an external resistor. The open load is indicated by a logic [1] in the SO data bit.

The *analog command* may be used to monitor the drain voltage in the MOSFET ON state. By sourcing 2.0 mA of

current to the 1.5 kΩ resistor, the analog voltage on the SGn pin will be approximately:

$$V_{SGn} = I_{SGn} \times 1.5 \text{ k}\Omega + V_{DS}$$

As the voltage on the drain of the MOSFET increases, so does the voltage on the SGn pin. With the SGn pin selected as analog, the MCU may perform the A/D conversion.

Using this method for controlling unclamped inductive loads is not recommended. Inductive flyback voltages greater than  $V_{PWR}$  may damage the IC.

The SP0–SP7 pins of this device may also be used to send signals from one module to another. Operation is similar to the gate control of a MOSFET.

For LED applications a resistor in series with the LED is recommended but not required. The switch-to-ground inputs are recommended for LED application. To drive the LED use the following commands:

- *wetting current timer enable command* –Disable SGn wetting current timer
- *metallic command* –Set SGn to 16 mA

From this point forward the LED may be turned on and off using the *tri-state command*:

- *tri-state command* –Disable tri-state for SGn (LED ON)
- *tri-state command* –Enable tri-state for SGn (LED OFF)

These parameters are easily programmed via SPI commands in Normal mode.

## MULTIPLE 33993 DEVICES IN A MODULE SYSTEM

Connecting power to the 33993 and the MCU for Sleep mode operation may be done in several ways. [Table 20](#) shows several system configurations for power between the MCU and the 33993 and their specific requirements for functionality.

**Table 20. Sleep Mode Power Supply**

MCU $V_{DD}$	33993 $V_{DD}$	Comments
5.0 V	5.0 V	All wake-up conditions apply. (Refer to <a href="#">Sleep Mode</a> , page 17.)
5.0 V	0 V	SPI wake-up is not possible.
0 V	5.0 V	Sleep mode not possible. Current from $\overline{CS}$ pull up will flow through MCU to $V_{DD}$ that has been switched off. Negative edge of $\overline{CS}$ will put 33993 in Normal mode.
0 V	0 V	SPI wake-up is not possible.

Multiple 33993 devices may be used in a module system. SPI control may be done in parallel or serial. However when parallel mode is used, each device is addressed independently (refer to [MCU Interface Description](#), page 11). Therefore when sending the *sleep command*, one device will enter sleep before the other. For multiple devices in a system, it is recommended that the devices are controlled in serial (S0

from first device is connected to SI of second device). With two devices, 48 clock pulses are required to shift data in. When the  $\overline{\text{WAKE}}$  feature is used to enable the power supply, both  $\overline{\text{WAKE}}$  pins should be connected to the enable pin on the power supply. The  $\overline{\text{INT}}$  pins may be connected to one interrupt pin on the MCU or may have their own dedicated interrupt to the MCU.

The transition from Normal to Sleep mode is done by sending the *sleep command*. With the devices connected in serial and the *sleep command* sent, both will enter Sleep mode on the rising edge of  $\overline{\text{CS}}$ . When Sleep mode is entered, the  $\overline{\text{WAKE}}$  pin will be logic [1]. If either device wakes up, the  $\overline{\text{WAKE}}$  pin will transition low, waking the other device.

A condition exists where the MCU is sending the *sleep command* ( $\overline{\text{CS}}$  logic [0]) and a switch input changes state. With this event the device that detects this input will not transition to Sleep mode, while the second device will enter Sleep mode. In this case two *switch status commands* must be sent to receive accurate switch status data. The first *switch status command* will wake the device in Sleep mode. Switch status data may not be valid from the first *switch status command* because of the time required for the input voltage to rise above the 4.0 V input comparator threshold. This time is dependant on the impedance of S<sub>Gn</sub> or S<sub>Pn</sub> node. The second *switch status command* will provide accurate switch status information. It is recommended that software wait 10 ms to 20 ms between the two *switch status commands*, allowing time for switch input voltages to stabilize. With all switch states acknowledged by the MCU, the sleep sequence may be initiated. All parameters for Sleep mode should be updated prior to sending the *sleep command*.

The 33993 IC has an internal 5.0 V supply from  $V_{\text{PWR}}$  pin. A POR circuit monitors the internal 5.0 V supply. In the event

of transients on the  $V_{\text{PWR}}$  pin, an internal reset may occur. Upon reset the 33993 will enter Normal mode with the internal registers as defined in [Table 14](#), page 16. Therefore it is recommended that the MCU periodically update all registers internal to the IC.

### USING THE $\overline{\text{WAKE}}$ FEATURE

The 33993 provides a  $\overline{\text{WAKE}}$  output and wake-up input designed to control an enable pin on system power supply. While in the Normal mode, the  $\overline{\text{WAKE}}$  output is low, enabling the power supply. In the Sleep mode, the  $\overline{\text{WAKE}}$  pin is high, disabling the power supply. The  $\overline{\text{WAKE}}$  pin has a passive pull-up to the internal 5.0 V supply but may be pulled up through a resistor to  $V_{\text{PWR}}$  supply (see [Figure 16](#), page 24)

When the  $\overline{\text{WAKE}}$  output is not used the pin should be pulled up to the  $V_{\text{DD}}$  supply through a resistor as shown in [Figure 15](#), page 24.

During the Sleep mode, a switch closure will set the  $\overline{\text{WAKE}}$  pin low, causing the 33993 to enter the Normal mode. The power supply will then be activated, supplying power to the  $V_{\text{DD}}$  pin and the microprocessor and the 33993. The microprocessor can determine the source of the wake-up by reading the interrupt flag.

### COST AND FLEXIBILITY

Systems requiring a significant number of switch interfaces have many discrete components. Discrete components on standard PWB consume board space and must be checked for solder joint integrity. An integrated approach reduces solder joints, consumes less board space, and offers wider operating voltage, analog interface capability, and greater interfacing flexibility.
