

# LMH6586

## 32x16 Video Crosspoint Switch

### General Description

The LMH6586 is a non-blocking analog video crosspoint switch designed for routing standard NTSC or PAL composite video signals. The non-blocking architecture allows any of the 32 inputs to be connected to any of the 16 outputs, including any input that is already connected. Each input has an integrated DC restore clamp for biasing of the AC-coupled video signal. The output buffers have a common selectable gain setting of 1X or 2X and can drive loads of 150Ω.

The LMH6586 features two types of input signal detection for convenient monitoring of activity on any input channel. Video detection can be configured to indicate when either “presence of video” or “loss of video” is detected across the video threshold level controlled by a programmable register. Additionally, sync detection can be configured to indicate when “loss of sync” is detected across the sync threshold level controlled by a DC voltage input.

The switch configuration and other parameters are programmable via the I<sup>2</sup>C bus interface. The slave device address is configurable via two external pins allowing up to four LMH6586 devices, each with a unique address, on a common I<sup>2</sup>C bus. This helps facilitate expansion of the crosspoint matrix array size (e.g. 64 x 16). The LMH6586 operates from a common single 5V supply for its analog sections as well as its control logic and I<sup>2</sup>C interface. The LMH6586 is offered in a space-saving 80-pin TQFP.

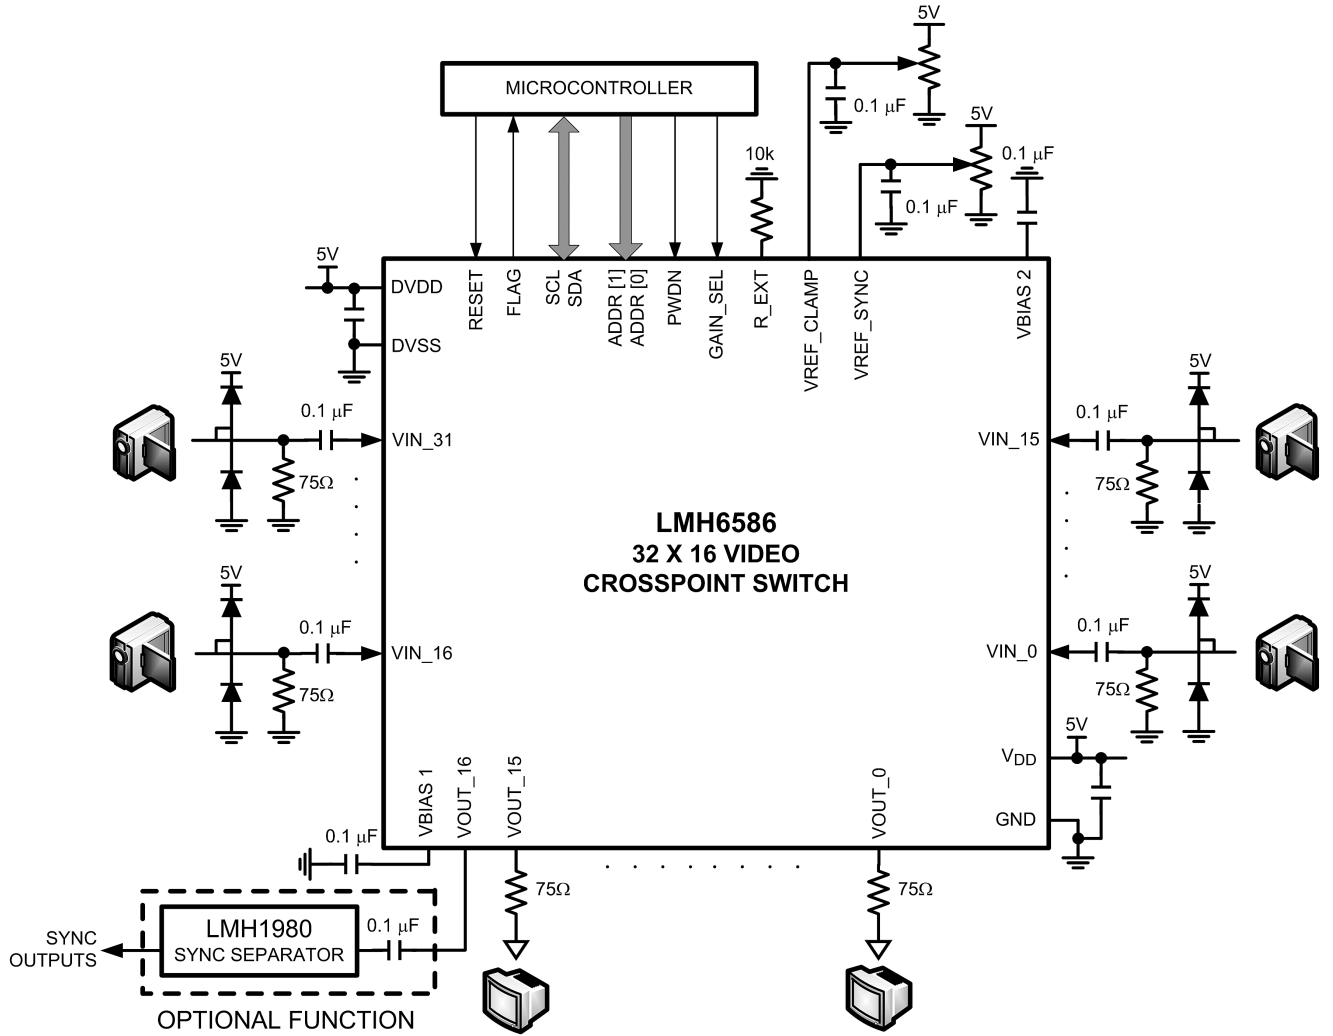

### Features

- 32 inputs and 16 outputs
- AC-coupled inputs with integrated DC restore clamp
- Individually addressable outputs
- Pin-selectable output buffer gain (1 V/V or 2 V/V)
- -3 dB bandwidth = 66 MHz
- DG = 0.05%, DP = 0.05° @ R<sub>L</sub> = 150Ω, A<sub>V</sub> = 2V/V
- -70 dB off-isolation @ 6 MHz
- Individual input and output shutdown modes
- Device power down mode
- Video detection with programmable threshold (8 levels)
- Sync detection with pin-configurable threshold
- 100 kHz I<sup>2</sup>C interface with 2-bit configurable slave address
- Single 5V supply operation
- Extra video output (VOUT\_16) for external video sync separator

### Applications

- CCTV security and surveillance systems
- Analog video routing

## Application Information

### FUNCTIONAL OVERVIEW

The LMH6586 is a non-blocking analog video crosspoint switch with 32 input channels and 16 output channels. The inputs have integrated DC restore clamp circuits for biasing the AC-coupled video inputs. The fully buffered outputs have selectable gain and can drive one back-terminated video load (150Ω). The LMH6586 includes an extra output (VOUT\_16) with 1X fixed gain that can be used to feed any input's video signal to an external video sync separator, such as the LMH1980 or LMH1981.

Each input and each output can be individually placed in shutdown mode by programming the input shutdown and output shutdown registers, respectively. Additionally, the PWDN pin (pin 70) can be set high to enable Power Down mode, which shuts down all input and output video channels while preserving all register settings.

The LMH6586 also features both video detection and sync detection functions on each input channel. Additional flexibility is provided by user-defined threshold levels for both video and sync detection features. The status of both detection schemes can be read from the video and sync detection status registers. Additionally, the FLAG output (pin 75) can be used to indicate if video detection or sync detection is triggered on any combination of input channels and detection types enabled by the user.

### OUTPUT BUFFER GAIN

The LMH6586 has an output buffer with a selectable gain of 1X or 2X. When the GAIN\_SEL input (pin 61) is set low, output channels 0–15 will have a gain of 1X. When it is set high, they will have a gain of 2X. Regardless of the gain select setting, output channel 16 has 1X fixed gain since the output is intended to drive an optional external sync separator through a 0.1 μF capacitor and no load termination.

### VIDEO DETECTION

This type of detection can be configured to indicate when an input's video signal is detected above the threshold level ("presence of video") or below the threshold level ("loss of video"). The video threshold voltage level is common to all 32 input channels and is selectable by programming register 0x1D. As shown in *Table 1*, the three LSBs (bits 2:0) of this register can be used to set the threshold level in 95 mV steps (typical) above to the sync tip level of the DC-restored input. Additionally, to prevent undesired triggering on high-frequency picture content, such as on-screen display (OSD) or text, the detection circuit actually analyzes a low-pass-filtered version of the video signal. The first-order RC filter is included on-chip and has a corner frequency of about 1 kHz.

Registers 0x04 to 0x07 (read-only) contain the video detection status bits for all 32 input channels. Any input (m) has a video detection status bit (VD\_m) that can flag high when either loss of video or presence of video is detected, depending on the respective invert control bit. Registers 0x0C to 0x0F contain the video detection invert control bits for all input channels. When the invert bit (VD\_INV\_m) is set to 0 (default setting), the respective status bit (VD\_m) will flag high when loss of video is detected on the input; otherwise, when the invert bit is set to 1, the status bit will flag high when presence of video is detected.

TABLE 1. Video Detect Threshold Voltage\*

Register 0x1D [2:0]			Threshold level above the sync tip level
0	0	0	491 mV
0	0	1	587 mV
0	1	0	683 mV
0	1	1	778 mV
1	0	0	873 mV
1	0	1	968 mV
1	1	0	1062 mV
1	1	1	1156 mV

\*See Video Detect parameters in Electrical Characteristics

The following example illustrates a practical use of video detection in a real-world system. A bank's ATM surveillance system could consist of a video camera, a LMH6586 crosspoint switch, a video recorder, and control system. When no one is using the ATM, the area being monitored by the camera could have strong backlighting, so the camera would output a normally high video level. When a person approaches the area, most of the backlighting would be blocked by the person and cause a measurable decrease in the video level. This change in camera's video level could be detected by the LMH6586, which could then flag the security system to begin recording of the activity. Once the person leaves the area, the LMH6586 could clear the flag.

### SYNC DETECTION

The LMH6586 also features a sync detection circuit that can indicate when an input's negative-going sync pulse is not detected below the threshold level ("loss of sync"). The sync threshold voltage level is common to all 32 input channels and is defined by the bias voltage on the VREF\_SYNC input (pin 65), which may be set using a simple voltage divider circuit. The recommended voltage level at the VREF\_SYNC pin is 350 mV to ensure proper operation.

Registers 0x00 to 0x03 (read-only) contain the sync detection status bits for all 32 input channels. Any input (m) has a sync detection status bit (SD\_m) that can flag high when a loss of sync is detected; otherwise, the status bit will be low to indicate presence of sync.

### DETECTION FLAG OUTPUT

The FLAG output (pin 75) can flag high if either video detection or sync detection is triggered based on the user-defined enable settings for the video and sync detection status bits. Any of the input's video detection status bits (VD\_m) and sync detection status bits (SD\_m) can be logically OR-ed into this single FLAG output pin. Registers 0x10 to 0x13 contain the video detection enable bits and registers 0x14 to 0x17 contain the sync detection enable bits for all input channels. Any input (m) has both a video detection enable bit (VD\_EN\_m) and a sync detection enable bit (SD\_EN\_m). When any enable bit is set low, the respective status bit will be excluded from the OR-ing function used to set the FLAG output; otherwise, when the enable bit is set high, the respective status bit will be included in the FLAG output function. Therefore, the FLAG will only logical-OR the status bits of the channel(s) and type(s) of detection that are specifically enabled by the user.

### SWITCH MATRIX

The LMH6586 uses 512 CMOS analog switches to form a 32 x 16 crosspoint switch. The LMH6586 is a non-blocking

crosspoint switch which means that any one of the 32 inputs can be routed to any of the 16 outputs. The switch can only be configured by programming through the I<sup>2</sup>C bus interface.

**DC RESTORATION**

Because the LMH6586 uses a single 5V supply and typical composite video signals contain signal components both above and below 0V (video blanking level), proper input signal biasing is required to ensure the video signal is within the operating range of the amplifier. To simplify the external biasing circuitry, each input of the LMH6586 has a dedicated DC restore clamp circuit to allow AC-coupled input operation using a 0.1 uF coupling capacitor. Please refer to *AC COUPLING* for details on how the coupling capacitor value was determined.

**AC COUPLING**

Each video input uses an integrated DC restore clamp circuit to servo the sync tip of the AC-coupled video input signal to the DC voltage received at the VREF\_CLAMP input (pin 66). For proper AC-coupled operation, the LMH6586 requires video signals with negative sync pulses. The VREF\_CLAMP level can be set in range of 300 mV to 1.0V using a voltage divider network. For optimum performance and reduced power consumption, it is recommended to set VREF\_CLAMP to 300 mV. Therefore, assuming a video input amplitude of 1V<sub>PP</sub>, the bottom of the sync tip level would be clamped to 300 mV above ground and the peak white video level would be at 1.3V.

**FIGURE 3. Input Video Signal Before DC Restore Clamp**

**FIGURE 4. Input Video Signal After DC Restore Clamp**

The equivalent DC restore clamp circuit is shown below.

**FIGURE 5. Clamp Circuit**

Typically the clamp voltage is set to 300 mV. During the sync pulse period, the clamp circuit amplifier sources current and the coupling capacitor will not discharge. However, during the active video period, the clamp amplifier will sink current and cause the coupling capacitor to discharge through the 75Ω resistor. To limit this discharge to an acceptable value we must choose an appropriate value of the AC coupling capacitor. The value of the AC coupling capacitor can be calculated as follows:

Cap Discharge Time  $T = \text{Line Period} - \text{Sync Period}$

$T = 63.5 \mu\text{s} - 4.7 \mu\text{s}$

$T = 58.8 \mu\text{s}$

Discharge current  $I = 1.37 \mu\text{A}$

Charge  $Q = I \cdot T$

$Q = 1.37 \mu\text{A} \cdot 58.8 \mu\text{s}$

$Q = 80.55 \text{ pC}$

$Q = C \cdot V$

$C = Q/V$

Typical acceptable voltage drop  $V = 0.1\% \text{ of } 700 \text{ mV}$

$V = 0.7 \text{ mV}$

Capacitor Value  $C = 80.55 \text{ pC} / 0.7 \text{ mV}$

$C = 0.115 \mu\text{F}$

Thus the suggested AC coupling capacitor value is 0.1 μF. A larger value will reduce line droop at the expense of longer input settling time.

**VIDEO INPUTS AND OUTPUTS**

The LMH6586 has 32 inputs which accept standard NTSC or PAL composite video signals. The input video signal should be AC coupled through a 0.1 μF coupling capacitor for proper operation. Each input is buffered before the switch matrix, which provides high input impedance. Input buffering enables any single output to be broadcasted to all 16 outputs at a time without loading of the input source. Each input buffer can be individually shut down using the input shutdown registers. When shutdown the input buffers are high impedance, which reduces power consumption and crosstalk.

The LMH6586 has 16 video outputs each of which is buffered through a programmable 1X or 2X gain output buffer. The outputs are capable of driving 150Ω loads. When the output gain is set to 1X (GAIN\_SEL = 0), the output signal sync tip is set to the VREF\_CLAMP voltage level; otherwise, when the gain is set to 2X (GAIN\_SEL = 1), the output signal sync tip is set to twice the VREF\_CLAMP level. Each output can be individually shut down using the output shutdown registers.

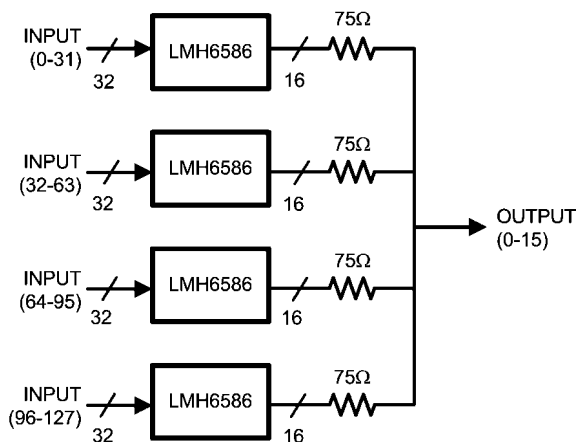

When shutdown the outputs are high impedance, which reduces power consumption and crosstalk, and also enables multiple outputs to be connected together for expanding the matrix array size. Note that output short circuit protection is not provided, so care must be taken to ensure only one output is active when output channels are tied together in expansion configurations.

### INPUT EXPANSION

The LMH6586 has the capability for creating larger switching matrices. Depending on the number of input and output channels required, the number of devices required can be calculated. To implement a 128 x 16 non-blocking matrix arrange the building blocks in a grid. The inputs are connected in parallel while the outputs are wired-or together. When using this configuration care must be taken to ensure that only one of the four outputs is active. The other three outputs should be placed in shutdown mode by using the appropriate shutdown bit in the output shutdown registers. This reduces output loading and the risk of output short circuit conditions, which can lead to device overheating and even damage to the channel or device.

The figure below shows the 128 input x 16 output switching matrix using four LMH6586 devices. To construct larger matrices use the same technique with more devices.

Because the LMH6586 has 2-bit configurable slave address inputs, up to four LMH6586 devices can be connected to a common I<sup>2</sup>C bus. For more devices additional I<sup>2</sup>C buses may be required.

30056945

FIGURE 6. 128 x 16 Crosspoint Array

### DRIVING CAPACITIVE LOAD

When many outputs are wired together, as in the case of expansion, each output buffer sees the normal load impedance as well as the impedance the other shutdown outputs. This impedance has a resistive and a capacitive component. The resistive components reduce the total effective load for the driving output. Total capacitance is the sum of the capacitance of all the outputs and depends on the size of the matrix. As the size of the matrix increases, the length of the PC board traces also increases, adding more capacitance. The output buffers have been designed to drive more than 30 pF of capacitance while still maintaining a good AC response. If the

output capacitance exceeds this amount then the AC response will be degraded. To prevent this, one option is to reduce the number of output wired-or together by using more LMH6586 device. Another option is to put a resistor in series with the output before the capacitive load to limit excessive ringing and oscillations.

A low pass filter is created from the series resistor (R) and parasitic capacitance (C) to ground. A single R-C does not affect the performance at video frequencies, however, in large system, there may be many such R-Cs cascaded in series. This may result in high frequency roll-off resulting in "softening of the picture". There are two solutions to improve performance in this case. One way is to design the PC board traces with some inductance between the R and C elements. By routing the traces in a repeating "S" configuration, the traces that are nearest each other will exhibit a mutual inductance increasing the total inductance. This series inductance causes the amplitude response to increase or peak at higher frequencies, offsetting the roll-off from the parasitic capacitance. Another solution is to add a small-value inductor between the R and C elements to add peaking to the frequency response.

### THERMAL MANAGEMENT

The LMH6586 operates on a 5V supply and draws a load current of approximately 300 mA. Thus it dissipates approximately 1.75W of power. In addition, each equivalent video load (150Ω) connected to the outputs should be budgeted 30 mW of power consumption.

The following calculations show the thermal resistance,  $\theta_{JA}$ , required, to ensure safe operation and to prevent exceeding the maximum junction temperature, given the maximum power dissipation.

$$P_{DMAX} = (T_{JMAX} - T_{AMAX})/\theta_{JA}$$

Where:

- $T_{JMAX}$  = Maximum junction temperature = 150°C
- $T_{AMAX}$  = Maximum ambient temperature = +85°C
- $\theta_{JA}$  = Thermal resistance of the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or:

$$P_{DMAX} = V_S \times I_{SMAX} + \sum_{i=1}^n (V_S - V_{OUTi}) \times \frac{V_{OUTi}}{R_{Li}}$$

Where:

- $V_S$  = Supply voltage = 5V
- $I_{SMAX}$  = Maximum quiescent supply current = 300 mA
- $V_{OUT}$  = Maximum output voltage of the application = 2.6V
- $R_L$  = Load resistance tied to ground = 150Ω
- $n$  = 1 to 16 channels

Calculating :

$$P_{DMAX} = 2.2656$$

The required  $\theta_{JA}$  to dissipate  $P_{DMAX}$  is  $(T_{JMAX} - T_{AMAX})/P_{DMAX}$

The table below shows the  $\theta_{JA}$  values with airflow and different heatsinks.

LMH6586VS 80-Pin TQFT LMHXPT Analog Video Crosspoint Board	0 LFPM @ 0.50 watt	0 LFPM @ 1.0 watt	0 LFPM @ 2.0 watt	0 LFPM @ 2.8 watt	225 LFPM @ 2.8 watt	500 LFPM @ 2.8 watt

### REXT RESISTOR

The REXT external resistor (pin 67) establishes the internal bias current and precise reference voltage for the LMH6586. For optimal performance, REXT should be a 10 k $\Omega$  1% precision resistor with a low temperature coefficient to ensure proper operation over a wide temperature range. Using a REXT resistor with less precision may result in reduced performance against temperature, supply voltage, input signal, or part-to-part variations.

### SYNC SEPARATOR OUTPUT

In addition to the 16 video outputs, the LMH6586 has an extra output (V\_OUT16) which can select any input channel. This channel's output buffer only has a gain of 1 since it is not meant to drive a 150 $\Omega$  video load. Instead, this video output can be AC coupled to a non-terminated input of an external video sync separator, such as National's LMH1980 or LMH1981. The sync separator can extract the synchronization (sync) timing signals, which can be useful for video triggering or phase-locked loop (PLL) clock generation circuits. Refer to the LMH1980 or LMH1981 datasheet for more information about these sync separator devices.

### I<sup>2</sup>C INTERFACE

A microcontroller can be used to configure the LMH6586 via the I<sup>2</sup>C interface. The protocol of the interface begins with a start pulse followed by a byte comprised of a seven-bit slave device address and a read/write bit as the LSB. The two lowest bits of the seven-bit slave address are defined by the external connections of inputs ADDR[1] (pin 72) and ADDR[0] (pin 71), where ADDR[0] is the least significant bit. Because there are four different combinations of the two ADDR pins, it's possible to have up to four different LMH6586 devices with unique slave addresses on a common I<sup>2</sup>C bus. See *I<sup>2</sup>C Device Slave Address Lookup Table*.

**I<sup>2</sup>C Device Slave Address Lookup Table**

ADDR[1] (pin 72)	ADDR[0] (pin 71)	7-bit I <sup>2</sup> C Slave Address (binary)
0	0	0000 000x
0	1	0000 001x
1	0	0000 010x
1	1	0000 011x

x = read/write bit; 0 = write sequence, 1 = read sequence

For example, if ADDR[1] is set low and ADDR[0] is set high, then the 7-bit slave address would be "0000 001" in binary. Therefore, the address byte for write sequences is 0x02 ("0000 0010") and the address byte read sequences is 0x03 ("0000 0011"). *Figure 7* and *Figure 8* show write and read sequences across the I<sup>2</sup>C interface.

### WRITE SEQUENCE

The write sequence begins with a start condition, which consists of the master pulling SDA low while SCL is held high. The slave device address is sent next. The address byte is made up of an address of seven bits (7:1) and the read/write bit (0). Bit 0 is low to indicate a write operation. Each byte that is sent is followed by an acknowledge (ACK) bit. When SCL is high the master will release the SDA line. The slave must pull SDA low to acknowledge. The address of the register to be written to is sent next. Following the register address and the ACK bit, the data byte for the register is sent. When more than one data byte is sent, the register pointer is automatically incremented to write to the next address location. Note that each data byte is followed by an ACK bit until a stop condition is encountered, indicating the end of the sequence.

The timing diagram for the write sequence is shown in *Figure 7*, which uses the 7-bit slave device address from the previous example above.

30056903

FIGURE 7. LMH6586 Write Sequence

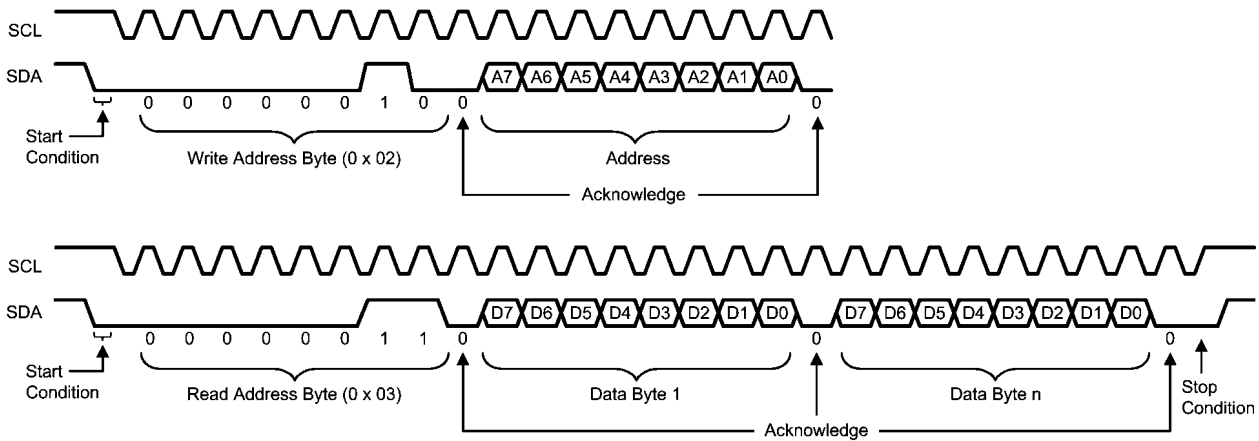

**READ SEQUENCE**

Read sequences are comprised of two I<sup>2</sup>C transfers shown. The first is the address access transfer, which consists of a write sequence that transfers only the address to be accessed. The second is the data read transfer, which starts at the address accessed in the first transfer and increments to the next address per data byte read until a stop condition is encountered.

The address access transfer consists of a start condition, the slave device address including the read/write bit (a zero, indicating a write), and the ACK bit. The next byte is the address to be accessed, followed by the ACK bit and the stop condition to indicate the end of the address access transfer.

The subsequent read data transfer consists of a start condition, the slave device address including the read/write bit (a one, indicating a read), and the ACK bit. The next byte is the data read from the initial access address. Subsequent read data bytes will correspond to the next increment address locations. Note that each data byte is followed by an ACK bit until a stop condition is encountered, indicating the end of the sequence.

The timing diagram for the read sequence is shown in Figure 8, which uses the 7-bit slave address from the previous examples.

## REGISTER DESCRIPTIONS

### Video and Sync Detection Status Registers

Registers 0x00 to 0x03 (read-only) contain the sync detection status bits for all 32 input channels. Any input (m) has a sync detection status bit (SD\_m) that can flag high when a loss of sync is detected; otherwise, the status bit will be low to indicate presence of sync.

Registers 0x04 to 0x07 (read-only) contain the video detection status bits for all 32 input channels. Any input (m) has a video detection status bit (VD\_m) that can flag high when either loss of video or presence of video is detected, depending on the respective invert control bit (see *Video Detection Invert Registers*). Assuming the default setting for the invert control bit, the status bit (VD\_m) will flag high when loss of video is detected on the input; otherwise, the status bit will be low indicating presence of video.

### Video and Sync Detection Control Registers

#### Video Detection Invert Registers:

Registers 0x0C to 0x0F contain the video detection invert control bits for all input channels. Any input (m) has an invert control bit that can invert the polarity of the video detection status bit (VD\_INV\_m). When the invert bit (VD\_INV\_m) is set to 0 (default), the respective status bit (VD\_m) will flag high to indicate loss of video on the input; otherwise, when the invert bit is set to 1, the status bit will flag high to indicate presence of video.

#### Video and Sync Detection Enable Registers:

Registers 0x10 to 0x13 contain the video detection enable bits and registers 0x14 to 0x17 contain the sync detection enable bits for all input channels. Any input (m) has both a video detection enable bit (VD\_EN\_m) and a sync detection enable bit (SD\_EN\_m). When any enable bit is set low, the respective status bit will be excluded from the OR-ing function used to

set the FLAG output; otherwise, when the enable bit is set high, the respective status bit will be included in the FLAG output function. Therefore, the FLAG will only logical-OR the status bits of the channel(s) and type(s) of detection that are specifically enabled by the user as described in *DETECTION FLAG OUTPUT*.

### Video Detection Threshold Control Register

The video threshold voltage level is common to all 32 input channels and is selectable by programming VDT[2:0] in register 0x1D. As shown in *Table 1*, the three LSBs (bits 2:0) of this register can be used to set the threshold level in 95 mV steps (typical) above to the sync tip level of the DC-restored input. Refer to *VIDEO DETECTION* for more information.

### Input and Output Shutdown Registers

Each input channel and each output channel can be individually placed in shutdown (power save) mode to reduce power consumption. Registers 0x18 to 0x1B contain the input shutdown bits (IN\_PS\_m) and registers 0x1E and 0x1F contain the output shutdown bits (OUT\_PS\_n), where “m” is any input channel and “n” is any output channel. To place any input or output channel in shutdown mode, the respective bit should be set high; otherwise, it should be set low for normal input or output operation. When in shutdown mode, the buffer (input or output) will be placed in a high-impedance state.

Note: To put the entire device in power save mode, the PWDN input (pin 70) should be set high; otherwise, it should be set low for normal operation.

### Video Input Selection Registers

Registers 0x20 to 0x30 are used to control the routing of the crosspoint switch. Each output has a dedicated input selection register, which can be programmed to select any input channel for routing to its respective output.

### LIFE SUPPORT POLICY

**NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE CHIEF EXECUTIVE OFFICER AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION.** As used herein:

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.
