

Digitally controlled audio processor

Features

- Input multiplexer
 - Four stereo, one mono input, and one differential input
 - Selectable input gain for optimal adaptation to different sources
- Fully programmable loudness function
- Volume control in 1dB steps including gain up to 16dB
- Zero crossing mute, soft mute and direct mute
- Bass and treble control
- Four speaker attenuators- four independent speakers control in 1dB steps for balance and fader facilities
- Pause detector programmable threshold
- All functions programmable via serial I²C bus

Description

The audioprocessor TDA7437N is an upgrade of the TDA731X audioprocessor family.

Due to a highly linear signal processing, using CMOS-switching techniques instead of standard bipolar multipliers, very low distortion and very

low noise are obtained. Several new features like softmute, and zero-crossing mute are implemented. The soft Mute function can be activated in two ways either via the serial bus (Mute byte, bit D0), or directly on pin 28 through an I/O line of the microcontroller

Very low DC stepping is obtained by use of a BICMOS technology.

V_O	Output voltage SDA acknowledge	$I_O = 1.6mA$		0.1	0.4	V

1. WIN represents the MUTE programming bit pair D6, D5 for the zero crossing window threshold
2. Internal pullup resistor to $Vs/2$; "LOW" = softmute active

Note: The ANGND and DIGGND layout wires must be kept separated. A 50Ω resistor is recommended to be put as far as possible from the device.

The CLD - and CDR - can be short-circuited in applications providing 3 wires CD signal

Figure 3. CLD and CDR

CLD - = DIFFINLGND

CDR - = DIFFINRGND

3 I²C bus interface

Data transmission from the microprocessor to the TDA7437N, and vice versa, takes place through the 2 wires of the I²C BUS interface, consisting of the two lines SDA and SCL (pull-up resistors to positive supply voltage must be externally connected).

3.1 Data validity

As shown in [Figure 4](#), the data on the SDA line must be stable during the high period of the clock. The HIGH and LOW state of the data line can only change when the clock signal on the SCL line is LOW.

3.2 Start and stop conditions

As shown in [Figure 5](#) a start condition is a HIGH to LOW transition of the SDA line while SCL is HIGH. The stop condition is a LOW to HIGH transition of the SDA line while SCL is HIGH. A STOP conditions must be sent before each START condition.

3.3 Byte format

Every byte transferred to the SDA line must contain 8 bits. Each byte must be followed by an acknowledge bit. The MSB is transferred first.

3.4 Acknowledge

The master (microprocessor) puts a resistive HIGH level on the SDA line during the acknowledge clock pulse (see [Figure 6](#)). The peripheral (audioprocessor) that acknowledges has to pull-down (LOW) the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during this clock pulse. The audioprocessor which has been addressed has to generate an acknowledgment after the reception of each byte, otherwise the SDA line remains at the HIGH level during the ninth clock pulse time. In this case the master transmitter can generate the STOP information in order to abort the transfer.

3.5 Transmission without acknowledgment

To avoid detection of the acknowledge clock pulse of the audioprocessor, the microprocessor can use a simpler transmission: it simply waits one clock pulse, and sends the new data. This is less protected from any errors and will decrease the immunity to noise.

Figure 4. Data validity

Figure 5. Timing diagram of I²C Bus

Figure 6. Acknowledge on the I²C Bus

4 Software specification

4.1 Interface protocol

The interface protocol comprises of:

- A start condition (s)
- A chip address byte, (the LSB bit determines read (=1)/write (=0) transmission)
- A subaddress byte.
- A sequence of data (N-bytes + acknowledge)
- A stop condition (P)

ACK = Acknowledge; S = Start; P = Stop; I = Auto increment; X = Not used

Max clock speed 500kbts/s

ADDRpin open A = 0

ADDRpin close to Vs A = 1

4.2 Auto increment

If bit I in the subaddress byte is set to "1", the autoincrement of the subaddress is enabled.

4.3 Subaddress (receive mode)

Table 5. Subaddress (receive mode)

MSB								LSB	FUNCTION
X	X	X	I	A3	A2	A1	A0		
				0	0	0	0	Input selector	
				0	0	0	1	Loudness	
				0	0	1	0	Volume	
				0	0	1	1	Bass, Treble	
				0	1	0	0	Speaker attenuator LF	
				0	1	0	1	Speaker attenuator LR	
				0	1	1	0	Speaker attenuator RF	
				0	1	1	1	Speaker Attenuator RR	
				1	0	0	0	Input gain middle	
				1	0	0	1	Mute	

4.4 Transmitted data

Table 6. Send mode

MSB							LSB
X	X	X	X	X	SM	ZM	P

\bar{P} = Pause (Active low)

ZM = Zero crossing muted (HIGH active)

SM = Soft mute activated (HIGH active)

X = Not used

The transmitted data is automatically updated after each ACK.

Transmission can be repeated without new chipaddress.

4.5 Data byte specification

Table 7. Data byte specification

5 Mute and pause features

The TDA7437N provides three types of mute, controlled via I²C bus (see [Table 9](#) Mute byte register).

5.1 Soft mute

Bit **D0 = 1** → **Soft mute ON**

Bit **D0 = 0** → **Soft mute OFF**

It allows an automatic soft muting and unmuting of the signal.

The time constant is fixed by an external capacitor Csm inserted between pin Csm and ground.

Once the external capacitor is fixed, two different slopes (time constant) are selectable by programming of bit D1.

Bit **D1 = 0** → **fast slope (I=Imax)**

Bit **D1 = 1** → **slow slope (I=Imin)**

The soft mute generates a gradually decreasing signal, avoiding big click noise of an immediate high attenuation, without necessity to program a sequence of decreasing volume levels. A response example is reported in [Figure 11](#) (mute), and [Figure 12](#) (unmute). The final attenuation obtained with soft mute ON is 60dB typical. The used reference parameter is the delay time taken to reach 20dB attenuation (no matter what the signal level is).

Using a capacitor Csm = 22nF this delay is:

d = 1.8ms when selected Fast slope mode (bit D1=0)

d = 25 ms when selected Slow slope mode (bit D1=1)

In the application, the soft mute ON programming should be followed by programming of direct mute on (see [5.2](#)), in order to achieve a final 100dB attenuation. In addition to the I²C bus programming, the Soft Mute ON can be generated in a fast way by forcing a LOW level at pin SMEXT (TTL Level compatible). This approach is recommended for fast RDS AF switching.

The Soft Mute status can be detected via I²C bus, reading the Transmitted Byte, bit SM (see [Table 6](#)).

read bit SM = 1 soft mute status ON

read bit SM = 0 soft mute status OFF

5.2 Direct mute

bit **D3 = 1** Direct mute ON

bit **D3 = 0** Direct mute OFF

The direct mute bit forces an internal immediate signal connection to ground.

It is located just before the Volume/Loudness stage, and gives a typical 100dB attenuation.

5.3 Speakers mute

An additional direct mute function is included in the speakers attenuators stage.

The four output LF, RF, LR, RR can be separately muted by setting the speaker attenuator byte to the value 01111111 binary.

Typical attenuation level 100dB. This mute is useful for fader and balance functions. It should not be applied for system mute/unmute, because it can generate noise due to the offset of previous stages (bass / treble).

5.4 Zero crossing mute

bit **D2 = 1 D4 = 0** zero crossing mute ON

bit **D2 = 0 D4 = 0** zero crossing mute OFF

The mute activation/deactivation is delayed until the signal waveform crosses the DC zero level (Vref level).

The detection works separately for left and right channels (see [Figure 13](#) and [Figure 14](#)). Four different window thresholds are software selectable by two dedicated bits.

bit	D6	D5	Window
	0	0	Vref DC +/-280mV
	0	1	Vref DC +/-140mV
	1	0	Vref DC +/-70mV
	1	1	Vref DC +/-35mV

The zero crossing mute activation/deactivation starts when the AC signal level falls inside the selected window (internal comparator).

The zero crossing mute (and pause) detector is always active. It can be disabled, if the feature is not used, by forcing the bit **D4 = 1** Zero crossing and pause detector reset.

In this way the internal comparator logic is stopped, eliminating its switching noise.

The zero cross mute status is detected reading the transmitted byte bit ZM.

bit **ZM = 1** zero cross mute status ON

bit **ZM = 0** zero cross mute status OFF

5.5 Pause function

On chip is implemented by a pause detector block.

It uses the same 4 windows threshold selectable for the zero crossing mute, bit D6,D5 byte MUTE (see above). The detector can be put into OFF by forcing bit **D4 = 1**, otherwise it is active.

Pause detector information is available at the PAUSE pin. A capacitor must be connected between the PAUSE pin and ground.

When the incoming signal is detected to be outside the selected window, the external capacitor is discharged. When the signal is inside the window, the capacitor is integrating up (see [Figure 15](#) and [Figure 16](#)).

- a) by reading directly the Pause pin level. The ON/OFF voltage threshold is 3.0V typical. Pause OFF = level low (< 3.0V) Pause ON = level high (; 3.0V)
- b) by reading via I2C bus the transmitted byte, bit PP = 0 pause active. P = 1 no pause detected. The external capacitor value fixes the time constant.

The pull up current is 25uV typical, with input signal

$V_{in} = 1V_{rms}$ --; V_{dc} pin pause = 15mV

$V_{in} = 0V_{rms}$ --; V_{dc} pin pause = 5.62V

For example choosing $C_{pause} = 100nF$ the charge up constant is about 22ms. Instead with $C_{pause} = 15nF$ the charge up constant is about 360µs.

The pause detection is useful in applications like RDS, to perform noiseless tuning frequency jumps, avoiding the use of the mute.

5.6 No symmetrical bass cut response

bit **D7** = **0** No symmetrical

bit **D7** = **1** Symmetrical

The bass stage has the option to generate an unsymmetrical response, for cut mode settings (bass level from -2db to -14dB)

For example using a T-type band pass external

The feature is useful for human ear equalization in a noisy environment, like a car.

See examples in [Figure 17](#) (symmetrical response) and [Figure 18](#) (unsymmetrical response).

5.7 Transmitted data (send mode)

bit **P** = **0** Pause active

bit **P** = **1** No pause detected

bit **ZM** = **1** Zero cross mute ON

bit **ZM** = **0** Zero cross mute OFF

bit **SM** = **1** Soft mute ON

bit **SM** = **0** Soft mute OFF

bit **ST** = **1** Stereo signal detected (input MPX)

bit **ST** = **0** Mono signal detected (input MPX)

The TDA7437N allows the reading of four info bits.

The type (stereo/mono) of received broadcasting signal is easily checked and displayed by using the **ST** bit.

The **P** bit check is useful in tuning jumps without signal muting.

The **SM** soft mute status becomes active immediately, when bit D0 is set to 1 (soft mute ON, MUTE byte) and not when the signal level has reached the 60 dB final attenuation.

5.8 TDA7437N I²C bus protocol

The protocol is standard I²C, using subaddress byte plus data bytes (as shown within [Chapter 4](#)).

The optional autoincrement mode allows to refresh all the bytes registers with transmission of a single subaddress, reducing drastically the total transmission time.

Without autoincrement, subaddress bit **I = 0**, to refresh all the bytes registers (10), it is necessary to transmit 10 times the chip address, the subaddress and the data byte.

Working with a 100Kb/s clock speed the total time would be :

$$[(9*3+2)*10]\text{bits} * 10\mu\text{s} = 2.9\text{ms}$$

Instead using autoincrement mode, subaddress bit **I=1**, the total time will be:

$$(9*12+2)*10\mu\text{s} = 1.1\text{ms}.$$

The autoincrement mode is useful also to refresh partially the data. For example to refresh the 4 speakers attenuators it is possible to program the subaddress Spkr LF (code XX010100), followed by the data byte of SPKR LF, LR, RF, RR in sequence.

Note: that the autoincrement mode has a module 16 counter, whereas the total used register bytes are 10.

It is not correct to refresh all the 10 bytes starting from a subaddress different than XX010000.

For example; using subaddress XX010010 (volume), the registers from Volume to Mute (see [Table 5](#)) are correctly updated, but the next two transmitted bytes, refer instead to the wanted Input selector, and Loudness are discharged. (the solution in this case is to send two separate patterns in autoincrement mode, the first composed by address, subaddress XX010010, 8 data bytes, and the second composed by address, subaddress XX010000, 2 data bytes).

With autoincrement disabled, the protocol allows the transmission in sequence of N data bytes of a specific register, without the necessity to resend the address and subaddress bytes, each time.

This feature can be implemented, for example, if a gradual volume change has to be performed (the MCU does not send the STOP condition, but keeps the TDA7437N communication active).

Warning: The TDA7437N always needs to receive a STOP condition, before beginning a new START condition. The device doesn't recognize a START condition if a previously active communication was not ended by a STOP condition.

5.9 I²C bus read mode

The TDA7437N sends the master a 1 byte "transmitted info" via I²C bus in read mode. The read mode is master activated by sending the chip address with LSB set to 1, followed by an acknowledge bit.

The TDA7437N recognizes the request. At the following master generated clock bits, the TDA7437N issues the transmitted info byte on the SDA data bus line (MSB transmitted first).

At the ninth clock bit the MCU master can:

- acknowledge the reception, starting in this way the transmission of another byte from the TDA7437N.
- no acknowledge, stopping the read mode communication.

5.10 Loudness stage

The previous SGS-THOMSON audioprocessors implemented a fixed loudness response, only ON/OFF sw programmable.

No possibility to change the loud boost rate at a certain volume level. The TDA7437N implements a fully programmable loudness control in 20 steps of 1dB.

It allows a customized loudness response for each application. The external network connected to the loudness pins LOUD_L and LOUD_R fixes the type of loudness response.

1. Simple capacitor. The loudness effect is only a boost of low frequencies. (see [Figure 19](#))
2. Second order loudness (boost of low and high frequencies).
3. Second order decreased type loudness (lower boost of low and high frequencies).
4. Second order modified type loudness (higher boost of low and high frequencies).

5.11 Treble stage

The treble stage is a simple high pass filter, its time constant is fixed by internal resistor (typically 50Kohm), and an external capacitor, connected between pins TREB_R/TREB_L and ground.

5.12 IN-OUT pins

The multiplexer output is available at OUT_R and OUT_L pins for the optional connection of an external graphic equalizer (TDA7316/TDA7317), surround chip (TDA7346) etc. The signal is fed in again at pins IN_L and IN-R. In the case of an application without any external devices, the pins OUT_L/OUT_R and IN_L/IN_R can be left unconnected, if bit D3 byte input selector is forced = 0 (DC connect). Instead if bit D3 is kept = 1 an external decoupling capacitor must be provided between OUTF/INR and OUTL/INR to avoid signal DC jumps, generating "clicking" output noise. The input impedance of the next volume stage is 44Kohm typical (minimum 31Kohm). A capacitor no lower than 1mF should be used.

5.13 Bass & mid filters

Several bass filter types can be implemented. Normally it is the basic T-type bandpass filter that is used. Starting from the filter component values (R1 internal and R2, C1, C2 external), the centre frequency F_c , the gain A_v at max bass boost and the filter Q factor are computed as follows:

$$F_c = \frac{1}{2 \cdot \pi \cdot \sqrt{R1 \cdot R2 \cdot C1 \cdot C2}}$$

$$A_v = \frac{R2 \cdot C2 + R2 \cdot C1 + R1 \cdot C1}{R2 \cdot C1 + R2 \cdot C2}$$

Vice versa fixed F_c , A_v , and R1 (internal typ. $\pm 30\%$), the external component values are

$$C1 = \frac{A_v - 1}{2 \cdot \pi \cdot R1 \cdot Q}$$

$$C2 = \frac{Q \cdot Q \cdot C1}{A_v - 1 - Q \cdot Q}$$

$$Q = \frac{\sqrt{(R1 \cdot R2 \cdot C1 \cdot C2)}}{R2 \cdot C1 + R2 \cdot C2}$$

$$R2 = \frac{A_v - 1 - Q \cdot Q}{2 \cdot \pi \cdot C1 \cdot F_c \cdot (A_v - 1) \cdot Q}$$

5.14 Input selector

The multiplexer selector can choose one of the following inputs:

- a differential CD stereo input.
- a mono input.
- four stereo input

The signal fed to the input pins must be decoupled via series capacitors. The minimum allowed value depends on the correspondent input impedance. For the CD diff input ($Z_i = 10\text{Kohm}$ worst case) a $C_{in} = 4.7\mu\text{F}$ is recommended. For the other inputs (70Kohm worst case, a $C_{in} = 1\mu\text{F}$ is recommended.

7 Package information

In order to meet environmental requirements, ST offers these devices in ECOPACK® packages. These packages have a lead-free second level interconnect. The category of second level interconnect is marked on the package and on the inner box label, in compliance with JEDEC standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label.

ECOPACK is an ST trademark. ECOPACK specifications are available at: www.st.com.
