## Description

Pericom Semiconductor's PI5C16212 is a 24 -bit bus exchange switch designed with Low On-Resistance allowing inputs to be connected directly to outputs. This device operates as a 24 -bit bus switch or a 12-bit exchanger that provides data exchanging between the four signal ports via the data select pins (S0-S2).

## Notes:

1. For Max. or Min. conditions, use appropriate value specified under Electrical Characteristics for the applicable device.
2. Typical values are at $\mathrm{Vcc}=5.0 \mathrm{~V}, \mathrm{Ta}=25^{\circ} \mathrm{C}$ ambient and maximum loading.
3. Not more than one output should be shorted at one time. Duration of the test should not exceed one second.
4. Measured by the voltage drop between A and B pin at indicated current through the switch. On-Resistance is determined by the lower of the voltages on the two ( $\mathrm{A}, \mathrm{B}$ ) pins.

## Notes:

1. For conditions shown as Max. or Min., use appropriate value specified under Electrical Characteristics for applicable device.
2. Typical values are at $\mathrm{Vcc}=5.0 \mathrm{~V},+25^{\circ} \mathrm{C}$ ambient.
3. This is the increase in supply current for each input that is at the specified TTL voltage level rather than Vcc or GND.
4. Per TTL driven input (Vin $=3.4 \mathrm{~V}$, control inputs only); A and B pins do not contribute to Icc.
5. This current applies to the control inputs only and represent the current required to switch internal capacitance at the specified frequency. The A and B inputs generate no significant AC or DC currents as they transition. This parameter is not tested, but is guaranteed by design.

## Switching Characteristics Over Operating Range

| Parameters | Description | Conditions | Com. |  | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Max. |  |
| $\begin{aligned} & \text { tPLH } \\ & \text { tpHL } \end{aligned}$ | Propagation Delay ${ }^{(1,2)}$, xAx to $\mathrm{xBx}, \mathrm{xBx}$ to xAx | $\begin{aligned} & \mathrm{C}_{\mathrm{L}}=50 \mathrm{pF} \\ & \mathrm{RL}=500-\mathrm{ohm} \end{aligned}$ |  | 0.25 | ns |
| $\begin{array}{\|l\|l\|} \hline \text { tPLH } \\ \text { tpHL } \end{array}$ | Propagation Delay, S to Ax or Bx |  | 1.5 | 7.5 |  |
| $\begin{aligned} & \mathrm{tPZH} \\ & \text { tPZL } \end{aligned}$ | Bus Enable Time, S to xAx or xBx |  | 1.5 | 7.0 |  |
| $\begin{array}{\|l\|l\|} \mathrm{tPHZ} \\ \mathrm{tPLZ} \end{array}$ | Bus Disable Time, S to xAx or xBx |  | 1.5 | 6.5 |  |

## Notes:

1. This parameter is guaranteed but not tested on Propagation Delays.
2. The bus switch contributes no propagational delay other than the RC delay of the On-Resistance of the switch and the load capacitance. The time constant for the switch alone is of the order of 0.25 ns for 50 pF load. Since this time constant is much smaller than the rise/fall times of typical driving signals, it adds very little propagational delay to the system. Propagational delay of the bus switch when used in a system is determined by the driving circuit on the driving side of the switch and its interaction with the load on the driven side.
