

## DDR 24-Bit to 48-Bit Registered Buffer

### Recommended Application:

- DDR Memory Modules for DDR 266/333/400
- Provides complete DDR DIMM logic solution with ICS93V857 or ICS95V857
- SSTL\_2 compatible data registers

### Product Features:

- Differential clock signals
- Supports SSTL\_2 class II specifications on inputs and outputs
- Low-voltage operation  
-  $V_{DD} = 2.3V$  to  $2.7V$
- Available in 114 ball BGA package.
- Advanced speed feature provides more timing margin for PC3200 applications
- Exceeds SSTVN32852 performance

## General Description

The 24-bit-to-48-bit **ICSSSTVA32852** is a universal bus driver designed for 2.3V to 2.7V  $V_{DD}$  operation and SSTL\_2 I/O levels, except for the LVCMOS RESET# input.

Data flow from D to Q is controlled by the differential clock (CLK/CLK#) and a control signal (RESET#). The positive edge of CLK is used to trigger the data flow and CLK# is used to maintain sufficient noise margins where as RESET#, an LVCMOS asynchronous signal, is intended for use at the time of power-up only. **ICSSSTVA32852** supports low-power standby operation. A logic level "Low" at RESET# assures that all internal registers and outputs (Q) are reset to the logic "Low" state, and all input receivers, data (D) and clock (CLK/CLK#) are switched off. Please note that RESET# must always be supported with LVCMOS levels at a valid logic state because VREF may not be stable during power-up.

To ensure that outputs are at a defined logic state before a stable clock has been supplied, RESET# must be held at a logic "Low" level during power up.

In the DDR DIMM application, RESET# is specified to be completely asynchronous with respect to CLK and CLK#. Therefore, no timing relationship can be guaranteed between the two signals. When entering a low-power standby state, the register will be cleared and the outputs will be driven to a logic "Low" level quickly relative to the time to disable the differential input receivers. This ensures there are no glitches on the output. However, when coming out of low-power standby state, the register will become active quickly relative to the time to enable the differential input receivers. When the data inputs are at a logic level "Low" and the clock is stable during the "Low"-to-"High" transition of RESET# until the input receivers are fully enabled, the design ensures that the outputs will remain at a logic "Low" level.

### Absolute Maximum Ratings

Storage Temperature	-65°C to +150°C
Supply Voltage	-0.5 to 3.6V
Input Voltage <sup>1</sup>	-0.5 to VDD +0.5
Output Voltage <sup>1,2</sup>	-0.5 to VDDQ +0.5
Input Clamp Current	±50 mA
Output Clamp Current	±50mA
Continuous Output Current	±50mA
VDD, VDDQ or GND Current/Pin	±100mA
Package Thermal Impedance <sup>3</sup>	55°C/W

**Notes:**

1. The input and output negative voltage ratings may be excluded if the input and output clamp ratings are observed.
2. This current will flow only when the output is in the high state level  $V_0 > V_{DDQ}$ .
3. The package thermal impedance is calculated in accordance with JESD 51.

Stresses above those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only and functional operation of the device at these or any other conditions above those listed in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.
