2. Reset Output
3. Ground
4. Reset Delay
5. Output

General Description

This device is a 5V low-drop fixed-voltage regulator. The maximum input voltage is 42V (65V, ≤ 400 ms). Up to an input voltage of 26V and for an output current up to 550mA it regulates the output voltage within a 2% accuracy. The short circuit protection limits the output current of more than 650mA. The device incorporates over voltage protection and temperature protection that disables the circuit at un-permissibly high temperatures.

Features

- Output Voltage tolerance $\pm 2\%$
- Low-drop Voltage
- Integrated Over Temperature Protection
- Reverse Polarity Protection
- Input Voltage up to 42V
- Over Voltage Protection up to 65V (≤ 400 ms)
- Short-Circuit Proof
- Suitable for use in Automotive Electronics
- Wide Temperature Range
- Adjustable Reset Time
- ESD Protection > 4KV

Note:

1. Drop voltage = $V_{IN} - V_{OUT}$ (measured when the output voltage has dropped 100 mV from the nominal value obtained at 13.5 V input)
2. Reset peak is always lower than 1.0 V.

Pin Definitions and Functions

Pin	Symbol	Function
1	Input	Block to ground directly on the IC with ceramic capacitor
2	Reset Output	The open collector output is connected to the 5 V output via an integrated resistor of 30 k Ω
3	GND	Internally connected to heatsink
4	Reset Delay	Connect a capacitor to ground for delay time adjustment
5	Output	5V, block to ground with 22 mF capacitor ESR, < 3W

Block Diagram

Application Description

The IC regulates an input voltage in the range of $5.5V < V_I < 36V$ to $V_{Onom} = 5.0V$. Up to 26V it produces a regulated output current of more than 550mA. Above 26V the save-operating-area protection allows operation up to 36V with a regulated output current of more than 300mA. Over voltage protection limits operation at 42V. The over voltage protection hysteresis restores operation if the input voltage has dropped below 36V. A reset signal is generated for an output voltage of $V_O < 4.5V$. The delay for power-on reset can be set externally with a capacitor.

Design Notes for External Components

An input capacitor C_I is necessary for compensation of line influences. The resonant circuit consisting of lead inductance and input capacitance can be damped by a resistor of approx. 1Ω W in series with C_I . An output capacitor C_O is necessary for the stability of the regulating circuit. Stability is guaranteed at values of $C_O \geq 22\mu F$ and ESR of $< 3\Omega$.

Circuit Description

The control amplifier compares a reference voltage, which is kept highly accurate by resistance adjustment, to a voltage that is proportional to the output voltage and drives the base of a series transistor via a buffer. Saturation control as a function of the load current prevents any over-saturation of the power element. If the output voltage decreases below 4.5V, an external capacitor C_D on pin 4 (Reset Delay) will be discharged by the reset generator. If the voltage on this capacitor drops below V_{DLR} , a reset signal is generated on pin 2 (Reset Output), i.e. reset output is set low. If the output voltage rises above 4.5V, C_D will be charged with constant current. After the power-on-reset time the voltage on the capacitor reaches V_{DU} and the reset output will be set high again. The value of the power-on-reset time can be set within a wide range depending of the capacitance of C_D .

The IC also incorporate a number of internal circuits for protection against:

- Overload
- Over Voltage
- Over temperature
- Reverse Polarity

Reset Timing

The power-on reset delay time is defined by the charging time of an external capacitor C_D which can be calculated as follows:

$$C_D = (\Delta t \times I_{D,C}) / \Delta V$$

C_D = Delay capacitors

Definitions: Δt = Reset delay Time t_{rd}

$I_{D,C}$ = Charge current, typical 14uA

ΔV = V_{DU} , typical 1.8V

V_{DU} = Upper reset timing threshold at C_D for reset delay time

$$t_{rd} = \Delta V \times C_D / I_{D,C}$$

The reset reaction time t_{rr} is the time it takes the voltage regulator to set the reset out LOW after the output voltage has dropped below the reset threshold. It is typical 1uS for delay capacitor of 47nF. For other values for C_D the reaction time can be estimated using the following equation:

$$t_{rr} \approx 20s/F \times C_D$$
