

FEATURES

- Withstands Transient Voltages Up to 200V/-200V
- Requires No Precision External Components
- Independently Monitors Two -48V Supplies for
 - Undervoltage Faults: $-38.5V \pm 1V_{MAX}$
 - Overvoltage Faults: $-70V \pm 1.5V_{MAX}$
- Accurately Detects Undervoltage Fault Recovery: $-43V \pm 0.5V_{MAX}$
- Monitors Two External Fuses
- Operates from -10V to -80V
- Tolerates DC Faults to -100V
- Tolerates Accidental Supply Reversal to 100V
- Small Footprint: 8-Lead MSOP Package
- Specified from -40°C to 85°C

APPLICATIONS

- Telecom Backplanes or Switch Cards
- Networking Backplanes or Switch Cards
- High Voltage Fuse Monitoring

DESCRIPTION

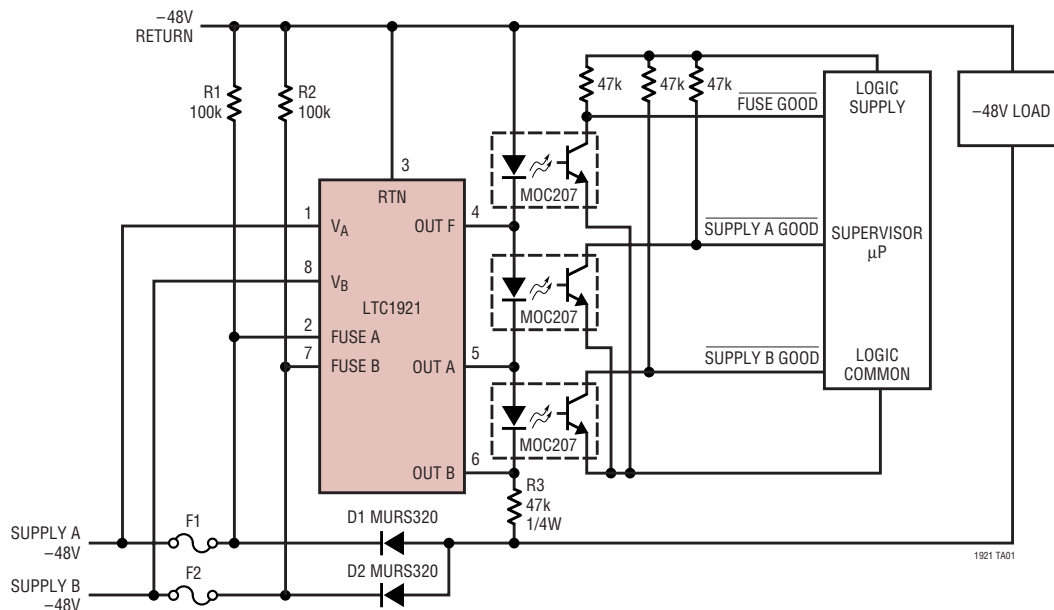

The LTC[®]1921 monitors two independent -48V supplies, including their fuses, and drives up to three optoisolators to indicate status, in accordance with standard backplane specifications. Requiring only three noncritical resistors and optoisolators, the LTC1921 replaces multiple voltage comparators, a voltage reference and several precision resistors.

The monitor features dual supply overvoltage and undervoltage detection circuits. The preset trip thresholds include overvoltage, undervoltage and undervoltage recovery that are guaranteed over temperature and meet or exceed common backplane specifications. Additional built-in circuitry detects the condition of supply fuses. Overvoltage and undervoltage detectors ignore fast supply transients, eliminating false detection. The LTC1921 operates from -10V to -80V with a typical power dissipation of less than 10mW.

The LTC1921 is available in 8-pin MSOP and SOIC packages.

 LTC and LT are registered trademarks of Linear Technology Corporation.

PIN FUNCTIONS

V_A (Pin 1): Supply to be Monitored. The voltage at this pin is compared to the valid supply voltage window and the result is output at OUT A (Pin 5). Supply current is drawn from V_A as well as from V_B (Pin 8).

FUSE A (Pin 2): This pin monitors the state of a fuse by comparing the voltage at this pin to the voltage at V_A (Pin 1). The result is output at OUT F (Pin 4).

RTN (Pin 3): Supply Return Reference. This pin must be at an equal or higher potential than the other pins and should be wired to the –48V return.

OUT F (Pin 4): This pin indicates the state of the external fuses by ORing the comparisons made to the FUSE A and FUSE B pins. If $V_{FUSEA} \cong V_A$ (V_{FUSEA} is within the specified window around V_A) and $V_{FUSEB} \cong V_B$, then OUT F will exhibit a high internal impedance to the RTN pin. If $V_{FUSEA} \neq V_A$ or $V_{FUSEB} \neq V_B$, then OUT F is shorted internally to the RTN pin and can shunt enough current to turn off an optoisolator or LED wired between these pins. OUT F should be clamped externally so that it cannot be driven more than 8V below RTN. This is done automatically by the optoisolator or LED diodes shown in the application circuits.

OUT A (Pin 5): Indicates the state of V_A. If V_A is within the specified voltage window (neither undervoltage nor overvoltage), OUT A will exhibit a high internal impedance to the

OUT F pin. If V_A is outside the specified overvoltage or undervoltage limits, then OUT A is shorted internally to the OUT F pin and can shunt enough current to turn off an optoisolator or LED wired between these pins. OUT A should be clamped externally so that it cannot be driven more than 8V below RTN. This is done automatically by the optoisolator or LED diodes shown in the application circuits.

OUT B (Pin 6): Indicates the state of V_B. If V_B is within the specified voltage window (neither undervoltage nor overvoltage), OUT B will exhibit a high internal impedance to the OUT A pin. If V_B is outside the specified overvoltage or undervoltage limits, then OUT B is shorted internally to the OUT A pin and can shunt enough current to turn off an optoisolator or LED wired between these pins. OUT B should be clamped externally so that it cannot be driven more than 8V below RTN. This is done automatically by the optoisolator or LED diodes shown in the application circuits.

FUSE B (Pin 7): This pin monitors the state of a fuse by comparing the voltage at this pin to the voltage at V_B (Pin 8). The result is output at OUT F (Pin 4).

V_B (Pin 8): Supply to be Monitored. The voltage at this pin is compared to the valid supply voltage window and the result is output at OUT B (Pin 6). Supply current is drawn from V_B as well as from V_A (Pin 1).

BLOCK DIAGRAM

APPLICATIONS INFORMATION

Supply Monitoring

The LTC1921 is designed to monitor dual -48V power supplies. This is accomplished with precision window comparators and an accurate bandgap reference, as well as internal level shifting circuitry. The comparators are preset to standard voltage thresholds in order to accurately verify the status of each supply. These comparators also include precision hysteresis which allows accurate determination of voltage recovery. Status of the two supplies are indicated by the OUT A and OUT B pins.

The supply window comparison works in a straightforward way (Figure 1). As long as each supply magnitude remains in the valid supply window (38.5V to 70V), the outputs will indicate a valid supply condition by exhibiting a high internal impedance. If a supply magnitude falls below the undervoltage threshold (38.5V), then its respective output will short internally (OUT A to OUT F or OUT B to OUT A) until that supply reaches the undervoltage recovery threshold, which is preset to -43V . At this time, the output will return to a high impedance state. If a supply magnitude rises above the overvoltage threshold (70V), then its respective output will short internally, just as with an undervoltage condition. The output will return to its nominal state when the supply overcomes the overvoltage hysteresis.

Monitoring for each supply, V_A and V_B , is independent of the condition of the other supply. The LTC1921 can be powered equally from either V_A , V_B or both supplies. This allows the LTC1921 to provide correct information at its outputs as long as at least one supply is functional, whether or not the fuses are intact (see Figure 2).

Undervoltage Lockout

If both supplies are active and their magnitude falls below 13V , or if only one supply is active and its magnitude falls below 19V , the LTC1921 will lock all outputs into a fault condition by closing all three output switches. This state will be held until one supply magnitude is driven above 19V or both are driven above 13V .

Fuse Monitoring

In addition to monitoring two supplies, the LTC1921 can monitor the condition of two supply fuses via the FUSE A (Pin 2) and FUSE B (Pin 7) inputs. Fuse monitoring is accomplished by comparing the potential at FUSE A to the potential at supply V_A and comparing the potential at FUSE B to the potential at supply V_B . If V_{FUSEA} is within the specified voltage window around V_A and V_{FUSEB} is within the specified voltage window around V_B , the OUT F pin will indicate that the fuses are intact by exhibiting a high

Figure 1. Supply Comparison

APPLICATIONS INFORMATION

internal impedance to the return (RTN) pin. The application must be designed so that an open fuse condition will force the fuse input (FUSE A or FUSE B) to be outside the specified window around the supply pins, such as with a weak pull-up resistor to RTN, so that the LTC1921 can properly indicate a fault at OUT F. If supply diodes that exhibit high reverse leakage, such as Schottky diodes, are used, then the values of the pull-up resistors must be reduced accordingly.

The FUSE A and FUSE B pins may also be used in conjunction with V_A and V_B for simple window comparison, provided that one of the circuit nodes to be compared can provide the small amount of supply current required to bias the IC. The LTC1921 is ideally suited for comparison functions in a circuit where only high supply voltages are available.

Output Pins

The output pins in the LTC1921 are designed to shunt external optoisolator diodes or LEDs during a supply or fuse fault condition. Up to three diodes may be used in

series, one for each output. In this configuration (Figure 2), a diode connected between OUT F and RTN will indicate the condition of both fuses. A diode connected between OUT A and OUT F will indicate the condition of supply A (V_A) and a diode connected between OUT B and OUT A will indicate the condition of supply B (V_B). A resistor connected from OUT B to the negative supply is required to bias the diodes. The LTC1921 is designed to allow the current from this resistor to flow through the diodes during normal supply conditions and intact fuses, and will shunt this current away from the proper diodes during a fault condition. These diodes will further clamp the output pin potentials to RTN in order to keep the outputs within rated voltages. If LEDs are used instead of optoisolators, they should be green since they will be lit when the supplies are within the proper voltage range.

The LTC1921 may be connected in such a way as to OR various outputs to allow the use of fewer optocouplers or LEDs (Figures 3a and 3b). One and two diode circuits are shown.
