

ECL/PECL Phase-Frequency Detectors

MAX9382/MAX9383

General Description

The MAX9382/MAX9383 are high-speed PECL/ECL phase-frequency detectors designed for use in high-bandwidth phase-locked loop (PLL) applications. The devices compare a single-ended reference (R) and a VCO (V) input and produce pulse streams on differential up (U) and down (D) outputs. When integrated, the difference of the output pulse streams provides a control voltage proportional to input phase or frequency difference. Guaranteed minimum short pulse duration completely eliminates minimum phase difference requirements during the lock condition, maximizing loop jitter performance.

The MAX9382/MAX9383 feature low propagation and reset delay, making them ideal for high-frequency clock synchronization use. The MAX9382 uses 100K logic levels, has a supply voltage range of $V_{CC} - V_{EE} = 4.2V$ to 5.5V, and is pin compatible with Motorola's MCK12140. The MAX9383 uses 10H logic levels with a supply voltage range of $V_{CC} - V_{EE} = 4.75V$ to 5.5V and is pin compatible with the MCH12140.

The MAX9382/MAX9383 are available in industry-standard 8-pin SO and space-saving 8-pin μ MAX packages.

Applications

Precision Clock Distribution
Central Office
DSLAM
DLC
Base Station
ATE

Functional Diagram

Features

- ◆ Guaranteed Minimum Pulse Width Eliminates Dead Band
- ◆ 450MHz Typical Bandwidth with up to $\pm\pi$ Phase Detection
- ◆ 75k Ω Internal Input Pulldown Resistors
- ◆ 44mA Typical Supply Current
- ◆ $\pm 2kV$ ESD Protection (Human Body Model)
- ◆ Pin Compatible with MCK12140 and MCH12140
- ◆ Available in 8-Pin μ MAX and SO Packages

Note 1: Measurements are made with the device in thermal equilibrium.

Note 2: Current into a pin is defined as positive. Current out of a pin is defined as negative.

Note 3: DC parameters are production tested at +85°C. DC limits are guaranteed by design and characterization over the full operating temperature range.

Note 4: All pins open except V_{CC} and V_{EE} .

Note 5: Guaranteed by design and characterization. Limits are set to ± 6 sigma.

Note 6: Phase offset is defined as the difference in propagation delay timing between the two input paths. It is measured between the U and D outputs at the differential crosspoint with a rising edge simultaneously applied at the R and V inputs.

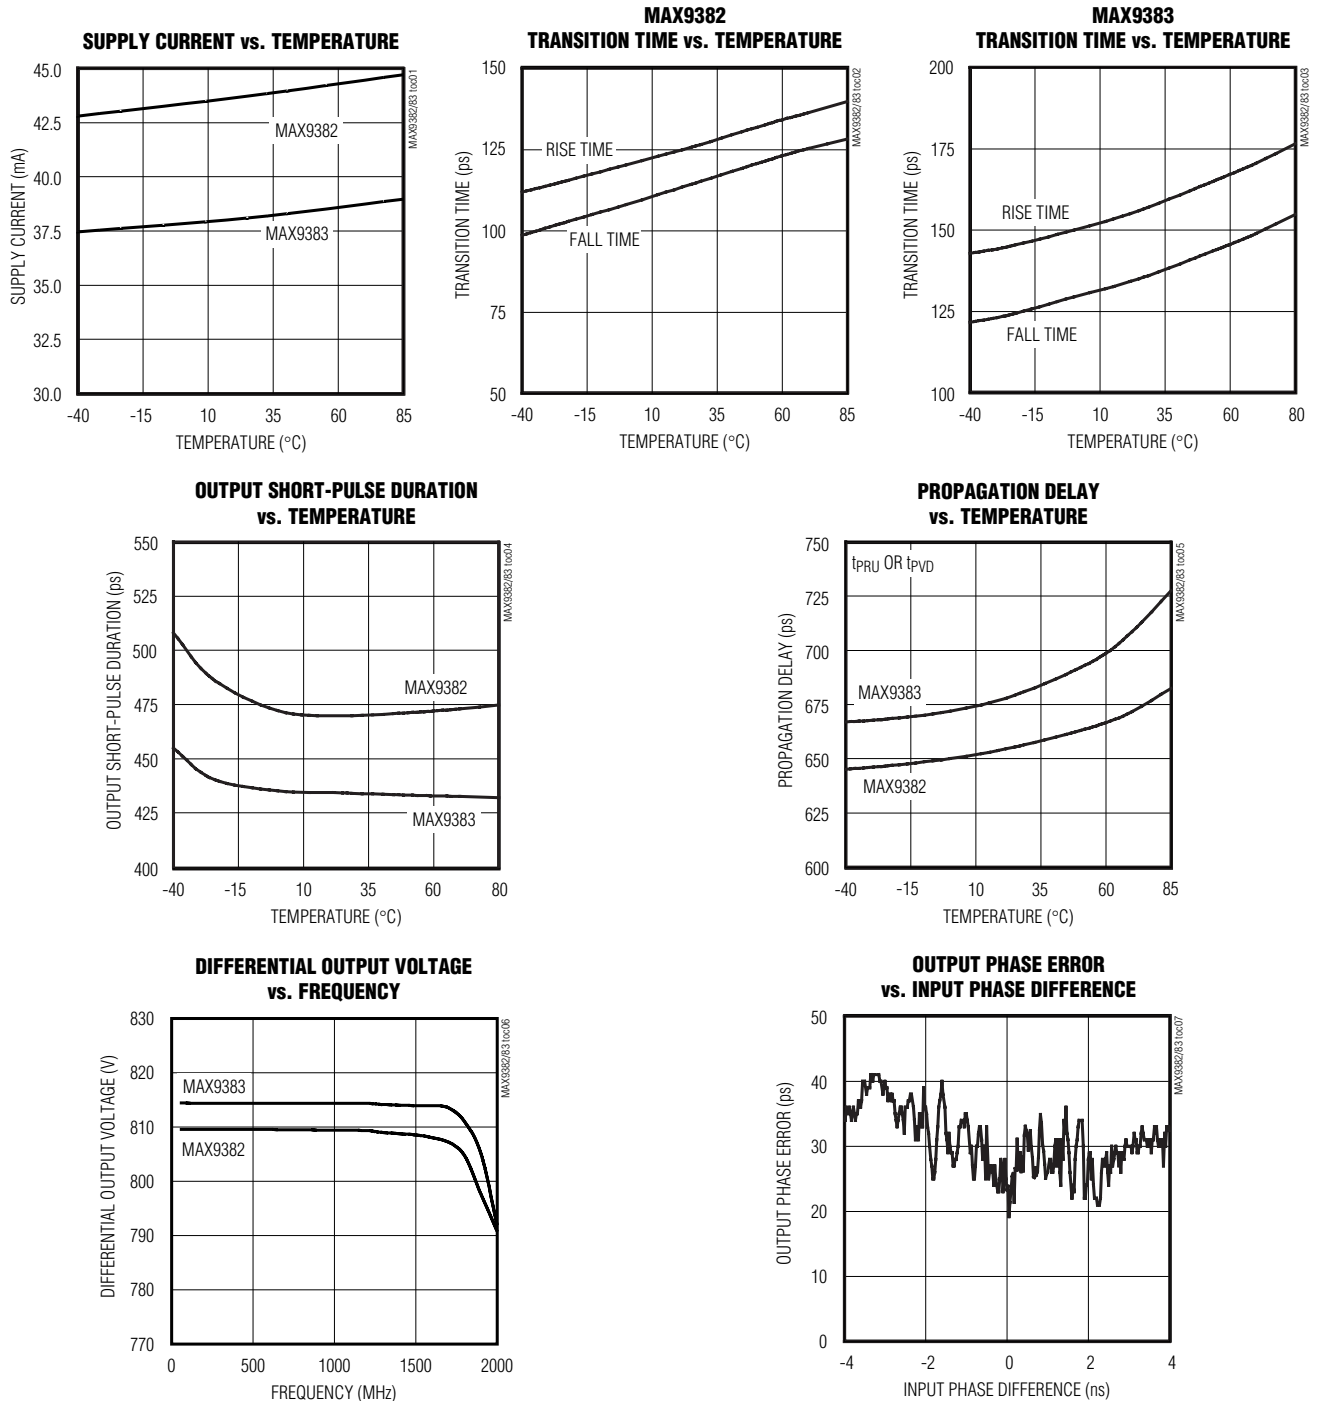

Note 7: Device jitter added to the input signal.

ECL/PECL Phase-Frequency Detectors

Typical Operating Characteristics

($V_{CC} - V_{EE} = +4.5V$ (MAX9382) or $V_{CC} - V_{EE} = +5.2V$ (MAX9383), $V_{IH} = V_{CC} - 1.00V$, $V_{IL} = V_{CC} - 1.60V$, $f_R = f_V = 100MHz$, outputs loaded with 50Ω to $V_{CC} - 2V$, $T_A = +25^\circ C$, unless otherwise noted.)

MAX9382/MAX9383

ECL/PECL Phase-Frequency Detectors

Pin Description

PIN	NAME	FUNCTION
1	\bar{U}	Inverting Up Output. Pulse stream is generated at this pin when $f_R > f_V$ or V lags R in phase. Terminate with 50Ω resistor to $V_{CC} - 2V$ or equivalent.
2	U	Noninverting Up Output. Pulse stream is generated at this pin when $f_R > f_V$ or V lags R in phase. Terminate with 50Ω resistor to $V_{CC} - 2V$ or equivalent.
3	\bar{D}	Inverting Down Output. Pulse stream is generated at this pin when $f_V > f_R$ or R lags V in phase. Terminate with 50Ω resistor to $V_{CC} - 2V$ or equivalent.
4	D	Noninverting Down Output. Pulse stream is generated at this pin when $f_V > f_R$ or R lags V in phase. Terminate with 50Ω resistor to $V_{CC} - 2V$ or equivalent.
5	V_{EE}	Negative Supply
6	V	Single-Ended VCO Input
7	R	Single-Ended Reference Input
8	V_{CC}	Positive Supply. Bypass from V_{CC} to V_{EE} with $0.1\mu F$ and $0.01\mu F$ ceramic capacitors. Place the capacitors as close to the device as possible with the smaller value capacitor closest to the device.

Detailed Description

The MAX9382/MAX9383 are high-speed phase or frequency detectors. The MAX9382 is compatible with 100K logic and has a power-supply range of $V_{CC} - V_{EE} = 4.2V$ to $5.5V$. The MAX9383 is compatible with 10H logic with a power-supply range of $V_{CC} - V_{EE} = 4.75V$ to $5.5V$. Both devices are specified to function from $-40^\circ C$ to $+85^\circ C$.

Each device is symmetrical; the R and V input functions may be swapped, together with the U and D output functions, and the inputs and outputs relabeled. Because of this device symmetry, a necessary condition for correct phase measurement operation is that the \bar{U} and \bar{D} outputs must both be high (state 0 condition) when the rising edge of the leading input is received. This condition is automatically generated when the two inputs are at different frequencies.

Phase Detection

The MAX9382/MAX9383 are intended for use in high-bandwidth PLL applications. These devices compare a single-ended VCO input (V) to a single-ended reference input (R) to determine the phase or frequency relationship between V and R. The device differential outputs U, \bar{U} and D, \bar{D} provide pulse trains with duty cycle proportional to the phase or frequency difference between R and V. These outputs are the up and down signals required to control the system VCO. Figure 1 shows typical waveforms when V leads R and V lags R. Subtracting and integrating these two outputs provide the necessary VCO control signal. Figure 3 shows the device transfer function obtained. The detector can

detect phase differences up to $\pm 2\pi$. The application frequency and the characteristics of the device internal reset circuits determine the usable input phase difference range.

Frequency Detection

Figure 4 is the state diagram for the MAX9382/MAX9383. With the two inputs at the same frequency, and input R leading input V, the device toggles between states 0 and 2. Similarly, if input R lags input V, the device toggles between states 0 and 1. With the two inputs at different frequencies, the output becomes a function of the frequency difference. The normalized ideal transfer function is given by:

$$V_{OUT_AVE} = 1 - \frac{f_R}{2f_V} \text{ for } f_V > f_R$$

and

$$V_{OUT_AVE} = 1 - \frac{f_V}{2f_R} \text{ for } f_R > f_V$$

Output Pulses

When inputs R and V are at the same phase and frequency, outputs U, \bar{U} and D, \bar{D} produce a stream of minimum duration pulses that occur at the rising edges of the input waveforms. This is the lock condition. If either input starts to lead the other in phase, the width of pulses on the corresponding output (U for R input, D for V input) increases in proportion to the phase difference. In a PLL implementation, these outputs direct the

ECL/PECL Phase-Frequency Detectors

MAX9382/MAX9383

Figure 1. Typical Waveforms when $f_R = f_V$

system VCO to increase or decrease frequency to maintain the lock condition.

The minimum output pulse duration is an important parameter for the design of the signal processing functions, which follow the phase detector. When controlling a charge-pump integrator, a detector can produce a dead-zone characteristic at the lock condition if the minimum pulse width is too short. MAX9382/MAX9383 eliminate this dead-zone characteristic, and the resulting phase offset at lock, by providing a well-defined minimum output pulse width.

Applications Information

The MAX9382/MAX9383 input and output levels are defined to be relative to the positive supply voltage. In ECL systems, the positive supply voltage is conventionally chosen to be system ground. This arrangement produces the best noise immunity, since ground is normally a system-wide reference voltage. Operate the devices with V_{CC} connected to ground and V_{EE} connected to a negative supply for ECL systems. With

Figure 2. Output Transition Times

PECL systems, connect V_{CC} to a positive supply and V_{EE} to ground.

Power-Supply Bypassing

Adequate power-supply bypassing is necessary to maximize the performance and noise immunity of ECL devices. This is particularly true of a PECL system where the power-supply voltage is used as a reference. Bypass V_{CC} to V_{EE} with high-frequency surface-mount ceramic 0.1 μ F and 0.01 μ F capacitors in parallel and as close to the device as possible, with the 0.01 μ F capaci-

ECL/PECL Phase-Frequency Detectors

Figure 3. Average Output Voltage vs. Phase Difference

tor closest to the device pins. Use multiple parallel vias for ground plane connection to minimize inductance.

Circuit Board Traces

Input and output trace characteristics affect the performance of ECL/PECL devices. Connect each of the detector's inputs and outputs to a 50Ω characteristic impedance trace. Avoid impedance discontinuities, maintain the distance between differential traces, avoid sharp corners, and keep the electrical length of the differential traces matched. This maximizes common-mode noise rejection and reduces signal skew. Trace vias cause impedance discontinuities, so keep the number of vias in the 50Ω traces to a minimum. Reduce reflections by maintaining the 50Ω characteristic impedance through connectors and across cables.

Output Termination

Terminate outputs through 50Ω to $V_{CC} - 2V$ or use an equivalent Thevenin termination. When a single-ended signal is taken from a differential output, terminate both outputs. For example, if the U output of the MAX9382 or MAX9383 is connected to a single-ended input, terminate both the U and \bar{U} outputs.
