

### FEATURES

- 3.0 GHz Fractional-N/1.2 GHz Integer-N
- 2.7 V to 3.3 V Power Supply
- Separate  $V_P$  Allows Extended Tuning Voltage to 5 V
- Programmable Dual Modulus Prescaler
  - RF: 4/5, 8/9
  - IF: 8/9, 16/17, 32/33, 64/65
- Programmable Charge Pump Currents
- 3-Wire Serial Interface
- Digital Lock Detect
- Power-Down Mode
- Programmable Modulus on Fractional-N Synthesizer
- Trade-Off Noise versus Spurious Performance
- Software and Hardware Power-Down

### APPLICATIONS

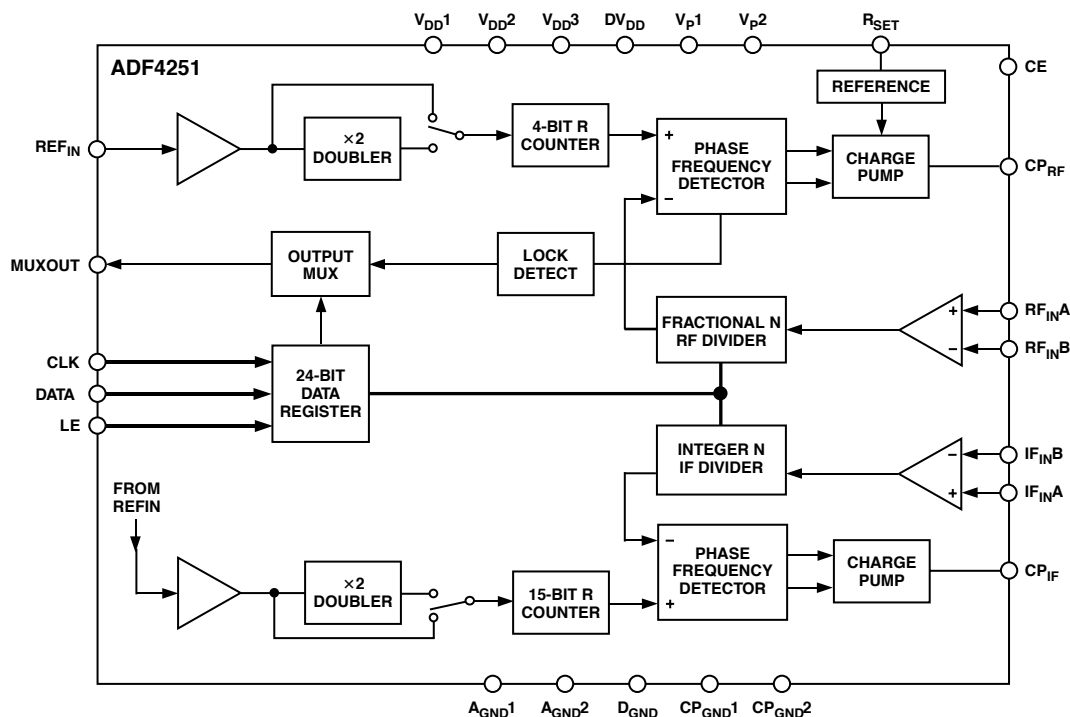

- Base Stations for Mobile Radio (GSM, PCS, DCS, CDMA, WCDMA)
- Wireless Handsets (GSM, PCS, DCS, CDMA, WCDMA, PHS)
- Wireless LANs
- Communications Test Equipment
- CATV Equipment

### GENERAL DESCRIPTION

The ADF4251 is a dual fractional-N/integer-N frequency synthesizer that can be used to implement local oscillators (LO) in the upconversion and downconversion sections of wireless receivers and transmitters. Both the RF and IF synthesizers consist of a low noise digital PFD (phase frequency detector), a precision charge pump, and a programmable reference divider. The RF synthesizer has a  $\Sigma$ - $\Delta$  based fractional interpolator that allows programmable fractional-N division. The IF synthesizer has programmable integer-N counters. A complete PLL (phase-locked loop) can be implemented if the synthesizer is used with an external loop filter and VCO (voltage controlled oscillator).

Control of all the on-chip registers is via a simple 3-wire interface. The devices operate with a power supply ranging from 2.7 V to 3.3 V and can be powered down when not in use.

## NOTES

<sup>1</sup>Operating Temperature Range (B Version): -40°C to +85°C.

<sup>2</sup>Use a square wave for frequencies less than F<sub>MIN</sub>.

<sup>3</sup>RF = 1 GHz, RF PFD = 10 MHz, MOD = 4095, IF = 500 MHz, IF PFD = 200 kHz, REF = 10 MHz, V<sub>DD</sub> = 3 V, V<sub>P1</sub> = 5 V, and V<sub>P2</sub> = 3 V.

<sup>4</sup>The in-band phase noise is measured with the EVAL-ADF4251EB2 Evaluation Board and the HP5500E Phase Noise Test System. The spectrum analyzer provides the REF<sub>IN</sub> for the synthesizer (f<sub>REFOUT</sub> = 10 MHz @ 0 dBm). F<sub>OUT</sub> = 1.74 GHz, F<sub>REF</sub> = 20 MHz, N = 87, MOD = 100, Channel Spacing = 200 kHz, V<sub>DD</sub> = 3.3 V, and V<sub>P</sub> = 5 V.

Specifications subject to change without notice.

## TIMING CHARACTERISTICS\* ( $V_{DD1} = V_{DD2} = V_{DD3} = DV_{DD} = 3\text{ V} \pm 10\%$ , $V_P1 = V_P2 = 5\text{ V} \pm 10\%$ , $GND = 0\text{ V}$ , unless otherwise noted.)

Parameter	Limit at $T_{MIN}$ to $T_{MAX}$ (B Version)	Unit	Test Conditions/Comments

## NOTES

<sup>1</sup>Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

<sup>2</sup>This device is a high performance RF integrated circuit with an ESD rating of <2 kΩ, and it is ESD sensitive. Proper precautions should be taken for handling and assembly.

<sup>3</sup>GND = CP<sub>GND1</sub>, A<sub>GND1</sub>, D<sub>GND</sub>, A<sub>GND2</sub>, and CP<sub>GND2</sub>.

## PIN CONFIGURATION

## ORDERING GUIDE

Model	Temperature Range	Package Option*
ADF4251BCP	-40°C to +85°C	CP-24
ADF4251BCP-REEL	-40°C to +85°C	CP-24
ADF4251BCP-REEL7	-40°C to +85°C	CP-24

\*CP = Lead Frame Chip Scale Package

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADF4251 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTIONS

Mnemonic	Function
CP <sub>RF</sub>	RF Charge Pump Output. This is normally connected to a loop filter that drives the input to an external VCO.
CP <sub>GND1</sub>	RF Charge Pump Ground
RF <sub>INA</sub>	Input to the RF Prescaler. This small signal input is normally taken from the VCO.
RF <sub>INB</sub>	Complementary Input to the RF Prescaler
A <sub>GND1</sub>	Analog Ground for the RF Synthesizer
MUXOUT	This multiplexer output allows either the RF or IF lock detect, the scaled RF or IF, or the scaled reference frequency to be accessed externally.
REF <sub>IN</sub>	Reference Input. This is a CMOS input with a nominal threshold of V <sub>DD</sub> /2 and an equivalent input resistance of 100 kΩ. This input can be driven from a TTL or CMOS crystal oscillator.
CE	Chip Enable. A Logic Low on this bit powers down the device and puts the charge pump outputs into three-state. A Logic High on this pin powers up the device, depending on the status of the software power-down bits.
D <sub>GND</sub>	Digital Ground for the Fractional Interpolator
CLK	Serial Clock Input. This serial clock is used to clock in the serial data to the registers. The data is latched into the shift register on the CLK rising edge. This input is a high impedance CMOS input.
DATA	Serial Data Input. The serial data is loaded MSB first with the three LSBs being the control bits. This input is a high impedance CMOS input.
LE	Load Enable, CMOS Input. When LE goes high, the data stored in the shift registers is loaded into one of the seven latches, the latch being selected using the control bits.
R <sub>SET</sub>	Connecting a resistor between this pin and ground sets the minimum charge pump output current. The relationship between I <sub>CP</sub> and R <sub>SET</sub> is:  $I_{CP\ MIN} = \frac{1.6875}{R_{SET}}$ Therefore, with R <sub>SET</sub> = 2.7 kΩ, I <sub>CP MIN</sub> = 0.625 mA.
A <sub>GND2</sub>	Ground for the IF Synthesizer
IF <sub>INB</sub>	Complementary Input to the IF Prescaler
IF <sub>INA</sub>	Input to the IF Prescaler. This small signal input is normally taken from the IF VCO.
DV <sub>DD</sub>	Positive Power Supply for the Fractional Interpolator Section. Decoupling capacitors to the ground plane should be placed as close as possible to this pin. DV <sub>DD</sub> must have the same voltage as V <sub>DD1</sub> , V <sub>DD2</sub> , and V <sub>DD3</sub> .
CP <sub>GND2</sub>	IF Charge Pump Ground
CP <sub>IF</sub>	IF Charge Pump Output. This is normally connected to a loop filter that drives the input to an external VCO.
V <sub>P2</sub>	IF Charge Pump Power Supply. Decoupling capacitors to the ground plane should be placed as close as possible to this pin. This voltage should be greater than or equal to V <sub>DD2</sub> .
V <sub>DD2</sub>	Positive Power Supply for the IF Section. Decoupling capacitors to the ground plane should be placed as close as possible to this pin. V <sub>DD2</sub> has a value 3 V ± 10%. V <sub>DD2</sub> must have the same voltage as V <sub>DD1</sub> , V <sub>DD3</sub> , and DV <sub>DD</sub> .
V <sub>DD3</sub>	Positive Power Supply for the RF Digital Section. Decoupling capacitors to the ground plane should be placed as close as possible to this pin. V <sub>DD3</sub> has a value 3 V ± 10%. V <sub>DD3</sub> must have the same voltage as V <sub>DD1</sub> , V <sub>DD2</sub> , and DV <sub>DD</sub> .
V <sub>DD1</sub>	Positive Power Supply for the RF Analog Section. Decoupling capacitors to the ground plane should be placed as close as possible to this pin. V <sub>DD1</sub> has a value 3 V ± 10%. V <sub>DD1</sub> must have the same voltage as V <sub>DD2</sub> , V <sub>DD3</sub> , and DV <sub>DD</sub> .
V <sub>P1</sub>	RF Charge Pump Power Supply. Decoupling capacitors to the ground plane should be placed as close as possible to this pin. This voltage should be greater than or equal to V <sub>DD1</sub> .

## CIRCUIT DESCRIPTION

### Reference Input Section

The reference input stage is shown in Figure 3. SW1 and SW2 are normally closed switches. SW3 is normally open. When power-down is initiated, SW3 is closed and SW1 and SW2 are opened. This ensures that there is no loading of the REF<sub>IN</sub> pin on power-down.

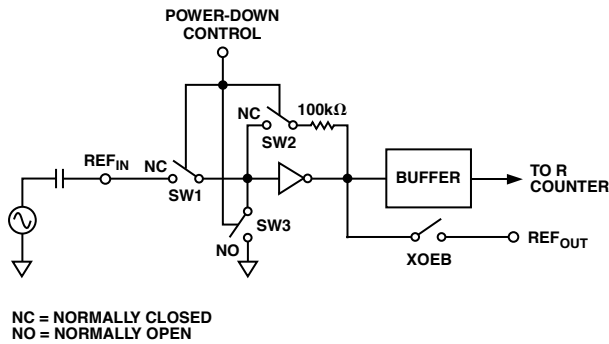

Figure 3. Reference Input Stage

### RF and IF Input Stage

The RF input stage is shown in Figure 4. The IF input stage is the same. It is followed by a two-stage limiting amplifier to generate the CML clock levels needed for the N counter.

Figure 4. RF Input Stage

### RF INT Divider

The RF INT CMOS counter allows a division ratio in the PLL feedback counter. Division ratios from 31 to 255 are allowed.

### INT, FRAC, MOD, and R Relationship

The INT, FRAC, and MOD values, in conjunction with the RF R counter, make it possible to generate output frequencies that are spaced by fractions of the RF phase frequency detector (PFD). The equation for the RF VCO frequency ( $RF_{OUT}$ ) is

$$RF_{OUT} = F_{PFD} \times \left( INT + \frac{FRAC}{MOD} \right) \quad (1)$$

where  $RF_{OUT}$  is the output frequency of external voltage controlled oscillator (VCO).

$$F_{PFD} = REF_{IN} \times \frac{(1+D)}{R} \quad (2)$$

$REF_{IN}$  = the reference input frequency,  $D$  = RF REF<sub>IN</sub> Doubler Bit,  $R$  = the preset divide ratio of the binary 4-bit programmable reference counter (1 to 15),  $INT$  = the preset divide ratio of the binary 8-bit counter (31 to 255),  $MOD$  = the preset modulus ratio of binary 12-bit programmable FRAC counter (2 to 4095), and  $FRAC$  = the preset fractional ratio of the binary 12-bit programmable FRAC counter (0 to MOD).

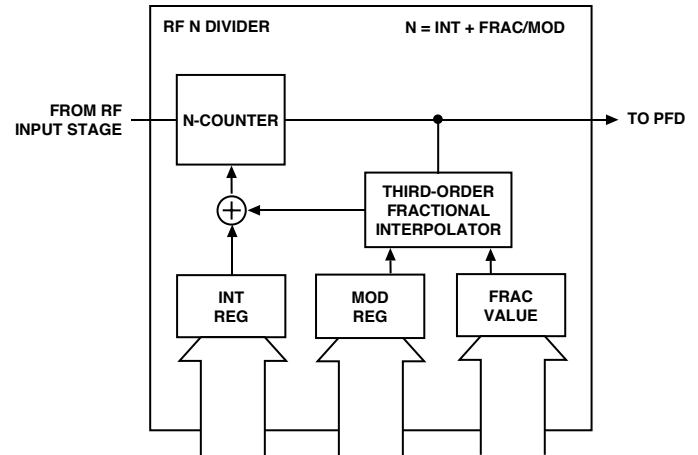

Figure 5. N Counter

### RF R Counter

The 4-bit RF R counter allows the input reference frequency ( $REF_{IN}$ ) to be divided down to produce the reference clock to the RF PFD. Division ratios from 1 to 15 are allowed.

### IF R Counter

The 15-bit IF R counter allows the input reference frequency ( $REF_{IN}$ ) to be divided down to produce the reference clock to the IF PFD. Division ratios from 1 to 32767 are allowed.

### IF Prescaler (P/P + 1)

The dual modulus IF prescaler ( $P/P + 1$ ), along with the IF A and B counters, enables the large division ratio,  $N$ , to be realized ( $N = PB + A$ ). Operating at CML levels, it takes the clock from the IF input stage and divides it down to a manageable frequency for the CMOS IF A and CMOS IF B counters.

### IF A and B Counters

The IF A CMOS and IF B CMOS counters combine with the dual modulus IF prescaler to allow a wide ranging division ratio in the PLL feedback counter. The counters are guaranteed to work when the prescaler output is 150 MHz or less.

### Pulse Swallow Function

The IF A and IF B counters, in conjunction with the dual modulus IF prescaler, make it possible to generate output frequencies that are spaced only by the reference frequency divided by  $R$ . See the Device Programming after Initial Power-Up section for examples. The equation for the IF VCO ( $IF_{OUT}$ ) frequency is

$$IF_{OUT} = [(P \times B) + A] \times F_{PFD} \quad (3)$$

where  $IF_{OUT}$  = the output frequency of the external voltage controlled oscillator (VCO),  $P$  = the preset modulus of the IF dual modulus prescaler,  $B$  = the preset divide ratio of the binary 12-bit counter (3 to 4095), and  $A$  = the preset divide ratio of the binary 6-bit swallow counter (0 to 63).  $F_{PFD}$  is obtained using Equation 2.

# ADF4251

## Phase Frequency Detector (PFD) and Charge Pump

The PFD takes inputs from the R counter and N counter and produces an output proportional to the phase and frequency difference between them. Figure 6 is a simplified schematic. The PFD includes a delay element that controls the width of the antibacklash pulse. This pulse ensures that there is no dead zone in the PFD transfer function and minimizes phase noise and reference spurs.

Figure 6. PFD Simplified Schematic

## MUXOUT and Lock Detect

The output multiplexer on the ADF4251 allows the user to access various internal points on the chip. The state of MUXOUT is controlled by M4, M3, M2, and M1 in the Master Register. Table VI shows the full truth table. Figure 7 shows the MUXOUT section in block diagram format.

Figure 7. MUXOUT Circuit

## Lock Detect

MUXOUT can be programmed for two types of lock detect: digital and analog. Digital is active high. The N-channel open-drain analog lock detect should be operated with an external pull-up resistor of 10 k $\Omega$  nominal. When lock has been detected, this output will be high with narrow low going pulses.

## Hardware Power-Down/Chip Enable

In addition to the software power-down methods described on pages 21 and 22, the ADF4251 also has a hardware power-down feature. This is accessed via the Chip Enable (CE) pin. When this pin is Logic High, the device is in normal operation. Bringing the CE pin Logic Low will power down the device. When this happens, the following events occur:

1. All active dc current paths are removed.
2. The RF and IF counters are forced to their load state conditions.
3. The RF and IF charge pumps are forced into three-state mode.
4. The digital lock detect circuitry is reset.
5. The RF<sub>IN</sub> and IF<sub>IN</sub> inputs are debiased.
6. The REF<sub>IN</sub> input buffer circuitry is disabled.
7. The serial interface input register remains active and capable of loading and latching data.

Bringing the CE pin back up again to Logic High will reinstate normal operation, depending on the software power-down settings.

## Input Shift Register

Data is clocked in on each rising edge of CLK. The data is clocked in MSB first. Data is transferred from the input register to one of seven latches on the rising edge of LE. The destination latch is determined by the state of the three control bits (C2, C1, and C0) in the shift register. These are the three LSBs: DB2, DB1, and DB0, as shown in Figure 1. The truth table for these bits is shown in Table I. Table II shows a summary of how the registers are programmed.

Table I. Control Bit Truth Table

Table VIII. IF R Divider Register Map

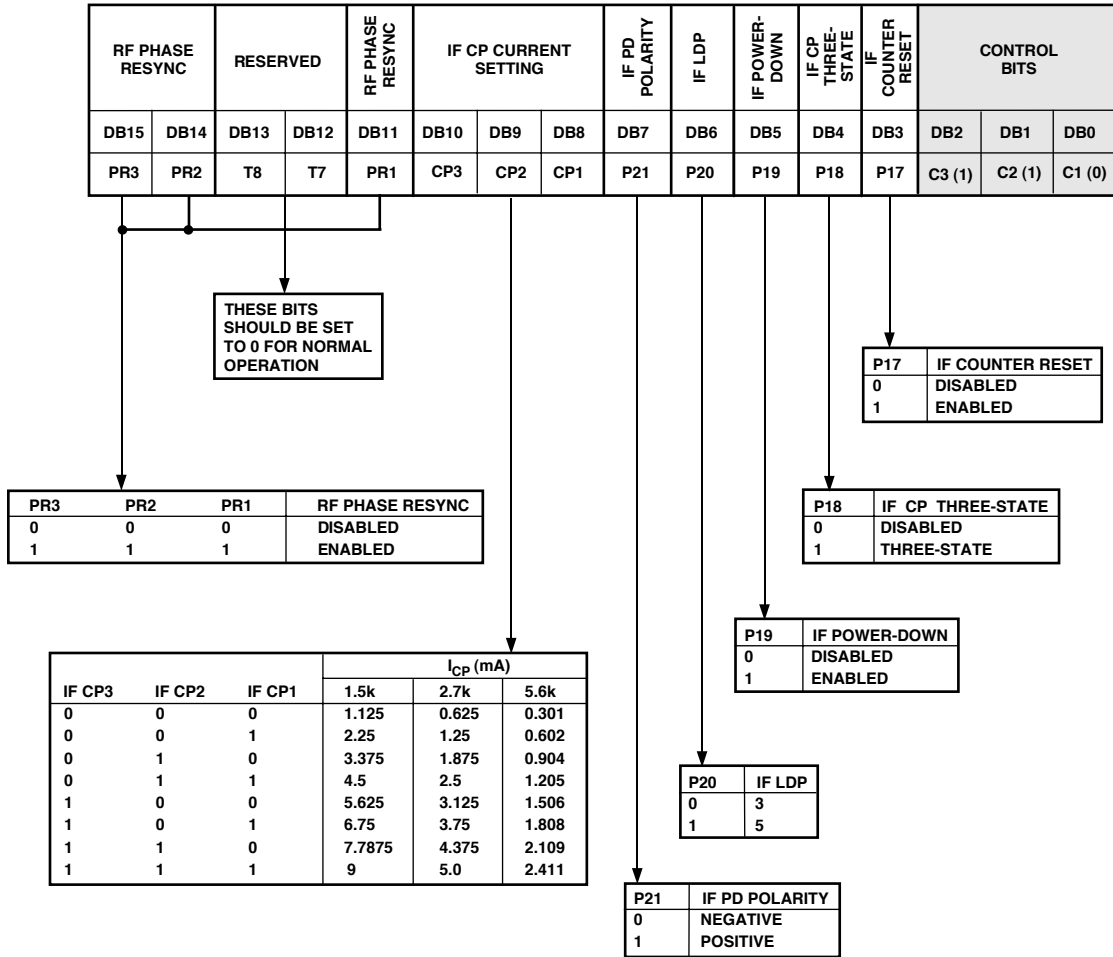

Table IX. IF Control Register Map

**RF N DIVIDER REGISTER****(Address R0)**

With R0[2, 1, 0] set to [0, 0, 0], the on-chip RF N Divider register will be programmed. Table III shows the input data format for programming this register.

**8-Bit RF INT Value**

These eight bits control what is loaded as the INT value. This is used to determine the overall feedback division factor. It is used in Equation 1.

**12-Bit RF FRAC Value**

These 12 bits control what is loaded as the FRAC value into the fractional interpolator. This is part of what determines the overall feedback division factor. It is used in Equation 1. The FRAC value must be less than or equal to the value loaded into the MOD register.

**RF R DIVIDER REGISTER****(Address R1)**

With R1[2, 1, 0] set to [0, 0, 1], the on-chip RF R Divider register will be programmed. Table IV shows the input data format for programming this register.

**RF Prescaler (P/P + 1)**

The RF dual-modulus prescaler (P/P + 1), along with the INT, FRAC, and MOD counters, determine the overall division ratio from the RF<sub>IN</sub> to the PFD input. Operating at CML levels, it takes the clock from the RF input stage and divides it down to a manageable frequency for the CMOS counters. It is based on a synchronous 4/5 core (see Table IV).

**RF REF<sub>IN</sub> Doubler**

Setting this bit to 0 feeds the REF<sub>IN</sub> signal directly to the 4-bit RF R counter, disabling the doubler. Setting this bit to 1 multiplies the REF<sub>IN</sub> frequency by a factor of 2 before feeding into the 4-bit RF R counter. When the doubler is disabled, the REF<sub>IN</sub> falling edge is the active edge at the PFD input to the fractional-N synthesizer. When the doubler is enabled, both the rising and falling edges of REF<sub>IN</sub> become active edges at the PFD input.

When the doubler is enabled and lowest spur mode is chosen, the in-band phase noise performance is sensitive to the REF<sub>IN</sub> duty cycle. The phase noise degradation can be as much as 5 dB for REF<sub>IN</sub> duty cycles outside a 45% to 55% range. The phase noise is insensitive to REF<sub>IN</sub> duty cycle in the lowest noise mode and in low noise and spur mode. The phase noise is insensitive to REF<sub>IN</sub> duty cycle when the doubler is disabled.

**4-Bit RF R Counter**

The 4-bit RF R counter allows the input reference frequency (REF<sub>IN</sub>) to be divided down to produce the reference clock to the phase frequency detector (PFD). Division ratios from 1 to 15 are allowed.

**12-Bit Interpolator Modulus**

This programmable register sets the fractional modulus. This is the ratio of the PFD frequency to the channel step resolution on the RF output.

**RF CONTROL REGISTER****(Address R2)**

With R2[2, 1, 0] set to [0, 1, 0], the on-chip RF control register will be programmed. Table V shows the input data format for programming this register. Upon initialization, DB15–DB11 should all be set to 0.

**Noise and Spur Setting**

The noise and spur setting (R2[15, 11, 06]) is a feature that allows the user to optimize his or her design either for improved spurious performance or for improved phase noise performance. When set to [0, 0, 0], the lowest spurs setting is chosen. Here, dither is enabled. This randomizes the fractional quantization noise so that it looks more like white noise than spurious noise. This means that the part is optimized for improved spurious performance. This operation would normally be used when the PLL closed-loop bandwidth is wide<sup>1</sup> for fast-locking applications. A wide loop filter does not attenuate the spurs to a level that a narrow<sup>2</sup> loop bandwidth would. When this bit is set to [0, 0, 1], the low noise and spur setting is enabled. Here, dither is disabled. This optimizes the synthesizer to operate with improved noise performance. However, the spurious performance is degraded in this mode compared to lowest spurs setting. To improve noise performance even further, another option is available that reduces the phase noise. This is the lowest noise setting [1, 1, 1]. As well as disabling the dither, it also ensures the charge pump is operating in an optimum region for noise performance. This setting is extremely useful where a narrow loop filter bandwidth is available. The synthesizer ensures extremely low noise and the filter attenuates the spurs. The Typical Performance Characteristics (TPCs) give the user an idea of the trade-off in a typical WCDMA setup for the different noise and spur settings.

**RF Counter Reset**

DB3 is the RF counter reset bit for the ADF4251. When this is 1, the RF synthesizer counters are held in reset. For normal operation, this bit should be 0.

**RF Charge Pump Three-State**

This bit puts the charge pump into three-state mode when programmed to a 1. It should be set to 0 for normal operation.

**RF Power-Down**

DB5 on the ADF4251 provides the programmable power-down mode. Setting this bit to a 1 will perform a power-down on both the RF and IF sections. Setting this bit to 0 will return the RF and IF sections to normal operation. While in software power-down, the part will retain all information in its registers. Only when supplies are removed will the register contents be lost.

When a power-down is activated, the following events occur:

1. All active RF dc current paths are removed.
2. The RF synthesizer counters are forced to their load state conditions.
3. The RF charge pump is forced into three-state mode.
4. The RF digital lock detect circuitry is reset.
5. The RF<sub>IN</sub> input is debiased.
6. The input register remains active and capable of loading and latching data.

**NOTES**

<sup>1</sup>Wide loop bandwidth is seen as a loop bandwidth greater than 1/10th of the RF<sub>OUT</sub> channel step resolution (F<sub>RES</sub>).

<sup>2</sup>Narrow loop bandwidth is seen as a loop bandwidth less than 1/10th of the RF<sub>OUT</sub> channel step resolution (F<sub>RES</sub>).

# ADF4251

## RF Phase Detector Polarity

DB7 in the ADF4251 sets the RF phase detector polarity. When the VCO characteristics are positive, this should be set to 1. When they are negative, it should be set to 0.

## RF Charge Pump Current Setting

DB9 and DB10 set the RF charge pump current setting. This should be set to whatever charge pump current the loop filter has been designed with (see Table V).

## RF Test Modes

These bits should be set to 0, 0, 0 for normal operation.

## MASTER REGISTER

### (Address R3)

With R3[2, 1, 0] set to 0, 1, 1, the on-chip master register will be programmed. Table VI shows the input data format for programming the Master Register.

## RF and IF Counter Reset

DB3 is the counter reset bit for the ADF4251. When this is 1, both the RF and IF R, INT, and MOD counters are held in reset. For normal operation, this bit should be 0. Upon powering up, the DB3 bit needs to be disabled, the INT counter resumes counting in “close” alignment with the R counter. (The maximum error is one prescaler cycle).

## Charge Pump Three-State

This bit puts both the RF and IF charge pump into three-state mode when programmed to a 1. It should be set to 0 for normal operation.

## Power-Down

R3[3] on the ADF4251 provides the programmable power-down mode. Setting this bit to a 1 will perform a power-down on both the RF and IF sections. Setting this bit to 0 will return the RF and IF sections to normal operation. While in software power-down, the part will retain all information in its registers. Only when supplies are removed will the register contents be lost.

When a power-down is activated, the following events occur:

1. All active dc current paths are removed.
2. The RF and IF counters are forced to their load state conditions.
3. The RF and IF charge pumps are forced into three-state mode.
4. The digital lock detect circuitry is reset.
5. The RF<sub>IN</sub> input and IF<sub>IN</sub> input are debiased.
6. The oscillator input buffer circuitry is disabled.
7. The input register remains active and capable of loading and latching data.

## MUXOUT Control

The on-chip multiplexer is controlled by R3[10–7] on the ADF4251. Table VI shows the truth table.

If the user updates the RF control register or the IF control register, the MUXOUT contents will be lost. To retrieve the MUXOUT signal, the user must write to the Master Register.

## IF N DIVIDER REGISTER

### (Address R4)

With R4[2, 1, 0] set to [1, 0, 0], the on-chip IF N divider register will be programmed. Table VII shows the input data format for programming this register.

## IF CP Gain

When set to 1, this bit changes the IF charge pump current setting to its maximum value. When the bit is set to 0, the charge pump current reverts back to its previous state.

## IF Prescaler

The dual-modulus prescaler ( $P/P + 1$ ), along with the IF A and IF B counters, determine the overall division ratio,  $N$ , to be realized ( $N = PB + A$ ) from the IF<sub>IN</sub> to the IF PFD input. Operating at CML levels, it takes the clock from the IF input stage and divides it down to a manageable frequency for the CMOS counters. It is based on a synchronous 4/5 core. See Equation 2 and Table VII.

## IF B and A Counter

The IF A and IF B counters, in conjunction with the dual modulus prescaler, make it possible to generate output frequencies that are spaced only by the reference frequency (REF<sub>IN</sub>), divided by R. The equation for the IF<sub>OUT</sub> VCO frequency is given in Equation 2.

## IF R DIVIDER REGISTER

### (Address R5)

With R5[2, 1, 0] set to 1, 0, 1, the on-chip IF R divider register will be programmed. Table VIII shows the input data format for programming this register.

## IF REF<sub>IN</sub> Doubler

Setting this bit to 0 feeds the REF<sub>IN</sub> signal directly to the 15-bit IF R counter. Setting this bit to 1 multiplies the REF<sub>IN</sub> frequency by a factor of 2 before feeding into the 15-bit IF R counter.

## 15-Bit IF R Counter

The 15-bit IF R counter allows the input reference frequency (REF<sub>IN</sub>) to be divided down to produce the reference clock to the IF phase frequency detector (PFD). Division ratios from 1 to 32767 are allowed.

## IF CONTROL REGISTER

### (Address R6)

With R6[2, 1, 0] set to 1, 1, 0, the on-chip IF control register will be programmed. Table IX shows the input data format for programming this register. Upon initialization, DB15–DB11 should all be set to 0.

## IF Counter Reset

DB3 is the IF counter reset bit for the ADF4251. When this is 1, the IF synthesizer counters are held in reset. For normal operation, this bit should be 0.

## IF Charge Pump Three-State

This bit puts the IF charge pump into three-state mode when programmed to a 1. It should be set to 0 for normal operation.

## IF Power-Down

DB5 on the ADF4251 provides the programmable power-down mode. Setting this bit to a 1 will perform a power-down on the IF section. Setting this bit to 0 will return the section to normal operation. While in software power-down, the part will retain all information in its registers. Only when supplies are removed will the register contents be lost.

When a power-down is activated, the following events occur:

1. All active IF dc current paths are removed.
2. The IF synthesizer counters are forced to their load state conditions.
3. The IF charge pump is forced into three-state mode.
4. The IF digital lock detect circuitry is reset.
5. The  $IF_{IN}$  input is debiased.
6. The input register remains active and capable of loading and latching data.

**IF Phase Detector Polarity**

DB7 in the ADF4251 sets the IF phase detector polarity. When the VCO characteristics are positive, this should be set to 1. When they are negative, it should be set to 0.

**IF Charge Pump Current Setting**

DB8, DB9, and DB10 set the IF charge pump current setting. This should be set to whatever charge pump current the loop filter has been designed with (see Table VII).

**IF Test Modes**

These bits should be set to 0, 0 for normal operation.

**RF Phase Resync**

Setting the Phase Resync Bits [15, 14, 11] to 1, 1, 1 enables the phase resync feature. With a fractional modulus of  $M$ , a fractional-N PLL can settle with any one of  $(2 \times \pi)/M$  valid phase offsets with respect to the reference input. This is different to integer-N (where the RF output always settles to the same static phase offset with respect to the input reference, which is zero ideally), but does not matter in most applications where all that is required is consistent frequency lock.

For applications where a consistent phase relationship between the output and reference is required (i.e., digital beamforming), the ADF4251 fractional-N synthesizer can be used with the phase resync feature enabled. This ensures that if the user programs the PLL to jump from frequency (and Phase) A to frequency (and Phase) B and back again to frequency A, the PLL will return to the original phase (Phase A).

When enabled, it will activate every time the user programs register R0 or R1 to set a new output frequency. However, if a cycle slip occurs in the settling transient after the phase re-resync operation, the phase resync will be lost. This can be avoided by delaying the resync activation until the locking transient is close to its final frequency. In the IF R Divider register, Bits R5[17-3] are used to set a time interval from when the new channel is programmed to the time the resync is activated. Although the time interval resolution available from the 15-bit IF R register is one  $REF_{IN}$  clock cycle, IF R should be programmed to be a value that is an integer multiple of the programmed MOD value to set a time interval that is at least as long as the RF PLL loop's lock time.

For example, if  $REF_{IN} = 26 \text{ MHz}$ ,  $MOD = 130$  to give  $200 \text{ kHz}$  output steps ( $F_{RES}$ ), and the RF loop has a settling time of  $150 \mu\text{s}$ , then IF R should be programmed to 3900, as:

$$26 \text{ MHz} \times 150 \mu\text{s} = 3900$$

Note that if it is required to use the IF synthesizer with phase resync enabled on the RF synth, the IF synth must operate with a PFD frequency of  $26 \text{ MHz}/3900$ . In an application where the IF synth is not required, the user should ensure that registers R4

and R6 are not programmed so that the rest of the IF circuitry remains in power-down.

**DEVICE PROGRAMMING AFTER INITIAL POWER-UP**  
After initially applying power to the supply pins, there are three ways to operate the device.

**RF and IF Synthesizers Operational**

All registers must be written to when powering up both the RF and IF synthesizer.

**RF Synthesizer Operational, IF Power-Down**

It is necessary to write to registers R3, R2, R1, and R0 only when powering up the RF synthesizer only. The IF side will remain in power-down until registers R6, R5, R4, and R3 are written to.

**IF Synthesizer Operational, RF Power-Down**

It is necessary to write only to registers R6, R5, R4, and R3 when powering up the IF synthesizer only. The RF side will remain in power-down until registers R3, R2, R1, and R0 are written to.

**RF Synthesizer: An Example**

The RF synthesizer should be programmed as follows:

$$RF_{OUT} = \left( INT + \frac{FRAC}{MOD} \right) \times F_{PFD} \tag{4}$$

where  $RF_{OUT}$  = the RF frequency output,  $INT$  = the integer division factor,  $FRAC$  = the fractionality, and  $MOD$  = the modulus.

$$F_{PFD} = \left( REF_{IN} \times \frac{1+D}{R} \right) \tag{5}$$

where  $REF_{IN}$  = the reference frequency input,  $D$  = the RF  $REF_{IN}$  Doubler Bit, and  $R$  = the RF reference division factor.

For example, in a GSM 1800 system where 1.8 GHz RF frequency output ( $RF_{OUT}$ ) is required, a 13 MHz reference frequency input ( $REF_{IN}$ ) is available and a 200 kHz channel resolution ( $F_{RES}$ ) is required on the RF output.

$$MOD = \frac{REF_{IN}}{F_{RES}}$$

$$MOD = \frac{13 \text{ MHz}}{200 \text{ kHz}} = 65$$

So, from Equation 5:

$$F_{PFD} = 13 \text{ MHz} \times \frac{1+0}{1} = 13 \text{ MHz}$$

$$1.8 \text{ GHz} = 13 \text{ MHz} \times \left( INT + \frac{FRAC}{65} \right)$$

where  $INT = 138$  and  $FRAC = 30$ .

**IF Synthesizer: An Example**

The IF synthesizer should be programmed as follows:

$$IF_{OUT} = \left[ (P \times B) + A \right] \times F_{PFD} \tag{6}$$

where  $IF_{OUT}$  = the output frequency of external voltage controlled oscillator (VCO),  $P$  = the IF prescaler,  $B$  = the B counter value, and  $A$  = the A counter value.

Equation 5 applies in this example as well.

# ADF4251

For example, in a GSM1800 system, where 540 MHz IF frequency output ( $IF_{OUT}$ ) is required, a 13 MHz reference frequency input ( $REF_{IN}$ ) is available and a 200 kHz channel resolution ( $F_{RES}$ ) is required on the IF output. The prescaler is set to 16/17. IF  $REF_{IN}$  doubler is disabled.

By Equation 5:

$$200 \text{ kHz} = 13 \text{ MHz} \times \frac{1+0}{R}$$

if  $R = 65$ .

By Equation 6:

$$540 \text{ MHz} = 200 \text{ kHz} \times [(16 \times B) + A]$$

if  $B = 168$  and  $A = 12$ .

## Modulus

The choice of modulus (MOD) depends on the reference signal ( $REF_{IN}$ ) available and the channel resolution ( $F_{RES}$ ) required at the RF output. For example, a GSM system with 13 MHz  $REF_{IN}$  would set the modulus to 65. This means that the RF output resolution ( $F_{RES}$ ) is the 200 kHz (13 MHz/65) necessary for GSM.

## Reference Doubler and Reference Divider

There is a reference doubler on-chip. This allows the input reference signal to be doubled. This is useful for increasing the PFD comparison frequency. Making the PFD frequency higher improves the noise performance of the system. Doubling the PFD frequency will usually result in an improvement in noise performance of 3 dB. It is important to note that the PFD cannot be operated above 30 MHz. This is due to a limitation in the speed of the  $\Sigma$ - $\Delta$  circuit of the N divider.

## 12-Bit Programmable Modulus

Unlike most other fractional-N PLLs, the ADF4251 allows the user to program the modulus over a 12-bit range. This means that the user can set up the part in many different configurations for his or her application, when combined with the reference doubler and the 4-bit R counter.

Take for example an application that requires 1.75 GHz RF and 200 kHz channel step resolution. The system has a 13 MHz reference signal.

One possible setup is feeding the 13 MHz directly to the PFD and programming the modulus to divide by 65. This would result in the required 200 kHz resolution.

Another possible setup is using the reference doubler to create 26 MHz from the 13 MHz input signal. This 26 MHz is then fed into the PFD. The modulus is now programmed to divide by 130. This also results in 200 kHz resolution. This would offer superior phase noise performance over the previous setup.

The programmable modulus is also very useful for multistandard applications. If a dual-mode phone requires PDC and GSM1800 standards, the programmable modulus is of huge benefit. PDC requires 25 kHz channel step resolution, whereas GSM1800 requires 200 kHz channel step resolution. A 13 MHz reference signal could be fed directly to the PFD. The modulus would be programmed to 520 when in PDC mode (13 MHz/520 = 25 kHz).

The modulus would be reprogrammed to 65 for GSM1800 operation (13 MHz/65 = 200 kHz). It is important that the PFD frequency remains constant (13 MHz). This allows the user to design one loop filter that can be used in both setups without running into stability issues. It is the ratio of the RF frequency to the PFD frequency that affects the loop design. Keeping this relationship constant and instead changing the modulus factor, results in a stable filter.

## Spurious Optimization and Fastlock

As mentioned in the Noise and Spur Setting section, the part can be optimized for spurious performance. However, in fast-locking applications, the loop bandwidth needs to be wide.

Therefore, the filter does not provide much attenuation of the spurious. The programmable charge pump can be used to get around this issue. The filter is designed for a narrow loop bandwidth so that steady-state spurious specifications are met. This is designed using the lowest charge pump current setting. To implement fastlock during a frequency jump, the charge pump current is set to the maximum setting for the duration of the jump. This has the effect of widening the loop bandwidth, which improves lock time. When the PLL has locked to the new frequency, the charge pump is again programmed to the lowest charge pump current setting. This will narrow the loop bandwidth to its original cutoff frequency to allow for better attenuation of the spurious than the wide loop bandwidth.

## Spurious Signals—Predicting Where They Will Appear

Just as in integer-N PLLs, spurs will appear at PFD frequency offsets on either side of the carrier (and multiples of the PFD frequency). In a fractional-N PLL, spurs will also appear at frequencies equal to the  $RF_{OUT}$  channel step resolution ( $F_{RES}$ ). The ADF4251 uses a high order fractional interpolator engine. This results in spurious signals also appearing at frequencies equal to 1/2 of the channel step resolution. For example, examine the GSM-1800 setup with a 26 MHz PFD and 200 kHz resolution. Spurs will appear at  $\pm 26$  MHz from the RF carrier (at an extremely low level due to filtering). Also, there will be spurs at  $\pm 200$  kHz from the RF carrier. Due to the fractional interpolator architecture used in the ADF4251, spurs will also appear at  $\pm 100$  kHz from the RF carrier. Harmonics of all spurs mentioned will also appear. With lowest spur setting enabled, the spurs will be attenuated into the noise floor.

## Prescaler

The prescaler limits the INT value. With  $P = 4/5$ ,  $N_{MIN} = 31$ . With  $P = 8/9$ ,  $N_{MIN} = 91$ .

The prescaler can also influence the phase noise performance. If  $INT < 91$ , a prescaler of 4/5 should be used. For applications where  $INT > 91$ ,  $P = 8/9$  should be used for optimum noise performance.

## Filter Design: ADIsimPLL

A filter design and analysis program is available to help users implement their PLL design. Visit [www.analog.com/pll](http://www.analog.com/pll) for a free download of the ADIsimPLL software. The software designs, simulates, and analyzes the entire PLL frequency domain and time domain response. Various passive and active filter architectures are allowed.

### IF Side Not In Use

If the IF side is not being used, the following pinout is recommended for the IF side:

Pin No.	Mnemonic	Description
14	A <sub>GND2</sub>	Short to all other ground pins.
15	IF <sub>INB</sub>	Leave open circuit. (This is biased up to V <sub>DD</sub> /2 internally.)
16	IF <sub>INA</sub>	Leave open circuit. (This is biased up to V <sub>DD</sub> /2 internally.)
19	CP_IF	Leave open circuit. (This is internally three-stated until power-up.)
20	V <sub>P2</sub>	Short to V <sub>P1</sub> . (V <sub>P1</sub> is the RF CP supply.)
21	V <sub>DD2</sub>	Short to V <sub>DD1</sub> (V <sub>DD1</sub> is the RF V <sub>DD</sub> supply.)

### INTERFACING

The ADF4251 has a simple SPI compatible serial interface for writing to the device. SCLK, SDATA, and LE control the data transfer. When LE (Latch Enable) goes high, the 24 bits that have been clocked into the input register on each rising edge of SCLK will be transferred to the appropriate latch. See Figure 1 for the Timing Diagram and Table I for the Control Bit Truth Table.

The maximum allowable serial clock rate is 20 MHz. This means that the maximum update rate possible for the device is 833 kHz or one update every 1.2 μs. This is certainly more than adequate for systems that will have typical lock times in hundreds of microseconds.

Figure 8. ADuC812 to ADF4251 Interface

### ADuC812 Interface

Figure 8 shows the interface between the ADF4251 and the ADuC812 microconverter. Since the ADuC812 is based on an 8051 core, this interface can be used with any 8051-based microcontroller. The microconverter is set up for SPI Master mode with CPHA = 0. To initiate the operation, the I/O port driving LE is brought low. Each latch of the ADF4251 needs (at most) a 24-bit word. This is accomplished by writing three 8-bit bytes from the microconverter to the device. When the third byte has been written, the LE input should be brought high to complete the transfer.

I/O port lines on the ADuC812 are also used to control power-down (CE input) and to detect lock (MUXOUT configured as lock detect and polled by the port input).

When operating in the mode described, the maximum SCLOCK rate of the ADuC812 is 4 MHz. This means that the maximum rate at which the output frequency can be changed will be 166 kHz.

Figure 9. Power-Down Circuit

# ADF4251

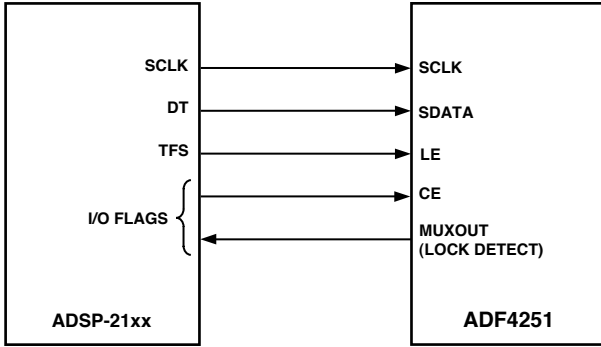

Figure 10. ADSP-21xx to ADF4251 Interface

## ADSP-2181 Interface

Figure 10 shows the interface between the ADF4251 and the ADSP-21xx digital signal processor. Each latch of the ADF4251 needs (at most) a 24-bit word. The easiest way to accomplish this using the ADSP-21xx family is to use the autobuffered transmit mode of operation with alternate framing. This provides a means for transmitting an entire block of serial data before an interrupt is generated. Set up the word length for eight bits and use three memory locations for each 24-bit word. To program each 24-bit latch, store the three 8-bit bytes, enable the autobuffered mode, and then write to the transmit register of the DSP. This last operation initiates the autobuffer transfer.

## Powerdown Circuit

The attached circuit in Figure 10 shows how to shut down the ADF4251 and the accompanying RF and IF VCO. The ADG701 switch goes closed circuit when a Logic High is applied to the IN input. The low cost switch is available in SOT-23 and SOIC packages.

## PCB DESIGN GUIDELINES FOR CHIP-SCALE PACKAGE

The leads on the chip-scale package (CP-24) are rectangular. The printed circuit board pad for these should be 0.1 mm longer than the package land length and 0.05 mm wider than the package land width. The land should be centered on the pad. This will ensure that the solder joint size is maximized.

The bottom of the chip-scale package has a central thermal pad. The thermal pad on the printed circuit board should be at least as large as this exposed pad. On the printed circuit board, there should be a clearance of at least 0.25 mm between the thermal pad and the inner edges of the pad pattern. This will ensure that shorting is avoided.

Thermal vias may be used on the printed circuit board thermal pad to improve thermal performance of the package. If vias are used, they should be incorporated in the thermal pad at 1.2 mm pitch grid. The via diameter should be between 0.3 mm and 0.33 mm, and the via barrel should be plated with 1 oz copper to plug the via.

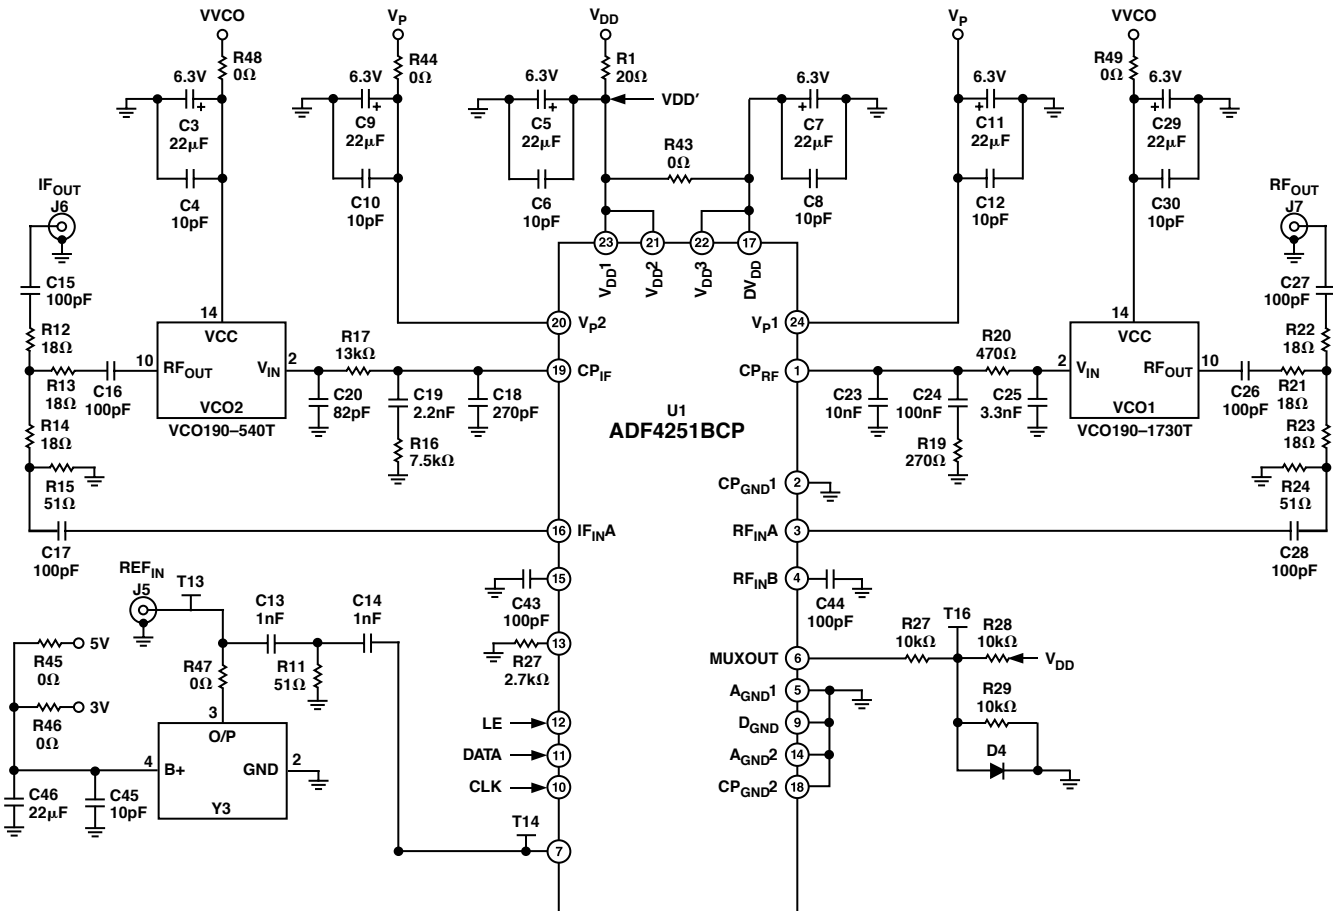

Figure 11. Typical PLL Circuit Schematic
