# Features

- 5 Smart Card Interfaces
  - Compliance with ISO 7816, EMV2000, GIE-CB and GSM Standards
  - Direct Connection to the Smart Cards Logic Level Shifters Short Circuit Current Limitation 4kV+ ESD Protection (MIL/STD 883 Class 3)
  - 1 or 2 Master Smart Card interfaces Synchronous Card support (with C4 and C8 Contacts) Card Detection and Automatic de-activation sequence on card extraction
  - 1 to 4 SAM/SIM cards (15 to 30mA each)
  - Programmable Voltage for each smart card Class A: 5V ±0.4V at 60 mA (±0.25V at 65 mA with VCC= 5V±10%) Class B: 3V ±0.2V at 60 mA Class C: 1.8V ±0.14V at 40mA
  - Low Ripple Noise: < 200 mV</p>
  - Programmable Activation Sequence
  - Automatic de-activation on card power-fail or over-current and system power-fail
  - Card Clock Stop High or Low for Card Power-down Modes
- Versatile Host Interface
  - Two Wire Interface (TWI) Link at 400kbit/s
    - Programmable Address allow up to 4 AT83C26 on the bus
  - Programmable Interrupt Output
- Reset Output Includes
  - Power-On Reset (POR)
  - Power-Fail Detector (PFD)
- Extended Voltage Operation: 3 to 5.5V
- Low Power Consumption
  - 5 mA Maximum Operating Current (without Smart Card)
    - 150 mA Maximum In-rush Current (each DC/DC)
    - 30 µA Typical Power-down Current (without Smart Card)
- 4 to 48 MHz Clock Input
- · System clock derived from the external clock input
- Industrial Temperature Range: -40 to +85°C
- Packages: QFN48, VQFP48

# Description

The AT83C26 is a smart card reader interface IC for smart card reader/writer applications such as EFT/POS terminals and set top boxes. It enables the management of any type of smart card from any kind of host. Up to 4 AT83C26 can be connected in parallel thanks to the programmable TWI address.

Its high efficiency DC/DC converters and low quiescent current in stand-by mode make it particularly suited to low power and portable applications. The reduced bill of material allows to lower significantly the system size and cost. A sophisticated protection system guarantees timely and controlled shutdown upon error conditions.

# **Pad Type Description**

To simplify the understanding of Figure 1. to Figure 8., a shortcut is possible by replacing the weak transistor by a 100k Ohms pull-up resistor, the medium transistor by a 10k Ohms pull-up resistor and the strong transistor by a 1k Ohms pull-up resistor.

### Input/Output with Pull-up Configuration (IO1, IO2, AUX1, AUX2)

This output type can be used as both an input and output without the need to reconfigure the port. This is possible because when the port outputs a logic high, it is weakly driven, allowing an external device to pull the pin low. When the port outputs a logic low state, it is driven strongly and able to sink a fairly large current.

Figure 1. Input/Output with Pull-up Configuration

# **Operational Modes**

### **TWI Bus Control**

The Atmel Two-Wire Interface (TWI) interconnects components on a unique two-wire bus, made up of one clock line and one data line with speeds of up to 400 Kbits per second, based on a byte-oriented transfer format.

The TWI-bus interface can be used:

- To configure the AT83C26
- To select interface
- To select the operating mode of the card: 1.8V, 3V or 5V
- To configure the automatic activation sequence
- To start or stop sessions (activation and de-activation sequences)
- To initiate a warm reset
- To control the clock to the card in active mode
- To control the clock to the card in stand-by mode (stop LOW, stop HIGH or running)
- To enter or leave the card stand-by or power-down modes
- To select the interface (connection to the host I/O/C4/C8)
- To request the status (card present or not, over-current and out of range supply voltage occurrence)
- To drive and monitor the card contacts by software
- To accurately measure the ATR delay when automatic activation is used
- Re-use the AT83C24 command set for the first DC/DC and smart card interface with the following changes:
  - •CKS extended to CONFIG2[0:3], CKS=8 selects CLK/3 and CKS>8 is reserved
  - •The slave address byte for TWI write commands is 0100  $\rm A_2A_110$  and 0100  $\rm A_2A_111$  for TWI read commands

# **TWI Commands**

**Frame Structure** The structure of the TWI bus data frames is made of one or a series of write and read commands completed by STOP.

Write commands to the AT83C26 have the structure:

ADDRESS BYTE + COMMAND BYTE + DATA BYTE(S)

Read commands to the AT83C26 have the structure: ADDRESS BYTE + DATA BYTE(S)

The ADDRESS BYTE is sampled on A2/CK and A1/RST **after each reset** (hard/soft/general call) but A2/CK, A1/RST can be used for transparent mode after the reset.

Figure 1. Data transfer on TWI bus

Address Byte The first byte to send to the device is the address byte. The device controls if the hardware address (A2/CK, A1/RST pins on reset) corresponds to the address given in the address byte (A2, A1 bits).

Figure 2. Address Byte

Up to 4 devices can be connected on the same TWI bus. Each device is configured with a different combination on A2/CK, A1/RST pins. The address byte of each device for read/write operations are listed below.

Table 2. Address Byte Values

| A2<br>(A2/CK pin) | A1<br>(A1/RST pin) | Address Byte<br>for<br>Read<br>Command | Address Byte<br>for<br>Write<br>Command |
|-------------------|--------------------|--|---|
| 0                 | 0                  | 0x43                                   | 0x42                                    |
| 0                 | 1                  | 0x47                                   | 0x46                                    |
| 1                 | 0                  | 0x4B                                   | 0x4A                                    |
| 1                 | 1                  | 0x4F                                   | 0x4E                                    |

# **RESET** pin

The TWI ADDRESS BYTE is sampled on A2/CK and A1/RST after a rising edge on  $\overline{\text{RESET}}$  pin. The delay between the rising edge and the sampling of A2/CK and A1/RST is t1.

The value for t1 is 22 CLK period.

The minimum value for t2 is 40 CLK period. During the t2 time, the TWI bus is not ready to receive a command.

The CLK period depends on the frequency of the signal on CLK pin.

The RESET pin is an I/O with Open Drain. The host IO pin connected to RESET must be an I/O open drain (with external pull-up) or an I/O open drain with internal pull up.

Figure 3. Timings after reset

# **BYPASS** pin

A high level on this pin activates a low power consumption mode.

At reset, the level on this pin must be fixed (VSS or VCC).

Before to set BYPASS pin, SHUTDOWNA and SHUTDOWNB bits must be set.

If SHUTDOWNA bit is set, DCDCA is switched off.

If SHUTDOWNB bit is set, DCDCB is switched off.

If SHUTDOWNA and SHUTDOWNB bits are set, the regulator is switched off.

If BYPASS pin is at a high level, the bandgaps are switched off.

### **Smart Card Interfaces**

The AT83C26 enables the management of up to 5 smart card interfaces. Due to shared IOs between SC2 and SC3, the user should choose between a full SC2 interface (with CC4 and CC8) or SC3 interface.

The SC2\_FULL bit in SC2\_CFG1 register is used to select the SC2/SC3 interfaces configuration.

12 **AT83C26** 

| Pin name   | SC2_FULL = 1<br>SC3 interface not available | SC2_FULL = 0<br>SC2 without CC4and CC8 + SC3 interface |
|------------|---|--|
| CPRES2     | CPRES2                                      | CPRES2   |
| CRST2      | CRST2                                       | CRST2  |

Table 3. SC2 and SC3 shared IOs

### **DCDC Converters**

The DC/DC A converter is used to provide smart card voltage for the SC1 interface (CVCC1).

The DC/DC B converter is used to provide smart card voltage for the SCn interfaces (n=2, 3, 4, 5).

DC/DC converters need a clock of 4MHz (see Section "Clock Controller"). Two internal oscillators (one for each converter) provide the DC/DC clocks.

The DC/DCB output is connected on 4 LDO regulators (Low Drop Output) to generate CVCCn voltage (n=2, 3, 4, 5).

# **Clock Controller**

The clock controller outputs six clocks:

- 1. Five clocks for CCLK1, CCLK2, CCLK3, CCLK4 and CCLK5. Four different sources can be used: CLK pin, DCCLK signal, CARDCKn bit (n=1, 2, 3, 4, 5) or A2/CK.
- 2. A DCCLK clock used for pads and deactivation sequence.

#### Clock controller for SCn (n=1, 2, 3, 4, 5)

The transparent mode with A2/CK pin is available on SCn interface. The CKSn[2:0] register is used to select this transparent mode between A2/CK and CCLKn. The bit CKSTOPn must be cleared to have CCLKn running according to CKSn[2:0].

Figure 4. Clock Block Diagram with Software Activation

# **CRST** controller

#### CRSTn for SCn interface (n=1, 2)

The CRSTn output pin is driven by the CARDRSTn bit value or by A1/RST pin.

Three modes are available:

- If the ARTn bit is reset, CRSTn pin is driven by CARDRSTn bit.
- If the ARTn bit is set, CRSTn pin is controlled and follows the "Automatic Reset Transition" (see Activation sequence page 25).
- A transparent mode with A1/RST pin.

Figure 5. CRSTn Block Diagram

#### CRSTn for SCn interface (n= 3, 4, 5)

The CRSTn output pin is driven by the CARDRSTn bit value (see SCn\_CFG2 register).

Two modes are available:

- If the ARTn bit is reset, CRSTn pin is driven by CARDRSTn bit.
- If the ARTn bit is set, CRSTn pin is controlled and follows the "Automatic Reset Transition" (see Activation sequence page 25).

Figure 6. CRSTn Block Diagram

If SC2\_FULL=1, the SC3 interface is not available.

# CIO, CC4, CC8 controller

#### CIO1, CC41, CC81 controller for SC1 interface

The CIO1, CC41, CC81 output pins are driven respectively by CARDIO1, CARDC41, CARDC81 bits values or by I/O1, I/O2, AUX1or AUX2 signals. This selection depends of the IODIS1 bit value (SC1\_INTERFACE register) and of IOSEL[3:0] bits value (IO\_SELECT register).

If IODIS1 is set, the CARDIO1 bit value is output on CIO1. The input selected by IOSEL for CIO1 is in High impedance state. CC41 and CC81 have the same behavior.

If IODIS1 is reset, data are bidirectional between the I/O1, I/O2, AUX1, AUX2 pins (see IO\_SELECT register) and CIO1, CC41, CC81 pins.

#### CIO2, CC42, CC82 controller for SC2 interface

The SC2\_FULL bit must be set to use CC42 and CC82.

#### CIOn controller for SCn interface (n=3, 4, 5)

The CIOn output pin is driven by CARDIOn bit values or by I/O1, I/O2, AUX1 or AUX2 signals. This selection depends of the IODISn bit value. If IODISn is reset, data are bidirectional between the I/O1, I/O2, AUX1, AUX2 pins (see IO\_SELECT register) and CIOn pins.

#### CIOn (n=1 to 5), CC41, CC81, CC42, CC82 transparent mode description

Two modes are available on CIOn, CC4n, CC8n signals:

- Bit control (a bit controls the output pin)
- Transparent mode (IO signal and CIO are linked after level shifter)

According to IO\_SELECT register value and IODISn bits values, one of 4 input pins (IO1, IO2, AUX1 or AUX2) is linked to the selected output.

The idle state is the high level. Each signal is bidirectional.

#### Transparent mode arbitration system

The first between IO and CIO to force a low level becomes the master.

The slave signal is grounded after t1 delay:

t1 max = 2\* (CLK period).

#### Figure 10. Bidirectional mode

The minimum delay for a pulse at 0 or 1 to be detected is between 0.5 and 1.5 CLK period (depending on arrival time).

If IO and CIO are both grounded, CIO becomes the master.

The minimum delay to switch of master without electrical conflict is equal to: t2 min = 4 \* (CLK period) + 2 \* (DCCLK period) \* (CLK period).

If a master switch appears before this minimum delay, the electrical conflict delay is: t2 = 2 \* (DCCLK period) \* (CLK period)

Figure 11. Electrical conflict

#### CCLKn and CIOn (n=1 to 5) slew rate control

Three registers SLEW\_CTRL\_1, SLEW\_CTRL\_2 and SLEW\_CTRL\_3 control the slew rate of the CIOn and CCLKn signals. Each signal has 2 control bits.

An automatic mode is proposed. The VCARDn[1:0] value is used to automatically adjust the slew rate.

For specific cases, like long wires between AT83C26 and smart card connector for example, the user can forced the slew rate.

The rising edge and the falling edge are modified with the slew rate control for CCLKn.

Only the rising edge is modified on CIOn with the slew rate control.

See Table 63. to Table 68. in Electrical Characteristics.

# **Card Presence Detection**

#### Card presence detection for SC1 interface

The card presence signal is connected on the CPRES1 pin. The polarity of card presence contact is selected with the CARDDET1 bit (see SC1\_CFG1 register). A programmable filtering is controlled with the CDS1[2-0] bits.

The internal pull-up on the CPRES1 pin can be disconnected in order to reduce the consumption. An external pull-up must be connected to Vcc. The PULLUP1 bit (see SC1\_CFG1 register) controls this feature.

Figure 12. SC1 presence Input

If the card presence contact is connected to Vcc, the internal pull-up must be disconnected and an external pull-down must be connected to the CPRES1 pin.

An interrupt can be generated if a card is inserted or extracted (see Section "Interrupts", page 30).

#### Card Presence Detection for SC2 interface

# **DC/DC converters**

#### **DC/DC A converter**

The DC/DC A converter is controlled by VCARD1[1:0], SHUTDOWNA, ICCADJA, STEPREGA, VCARD\_OK1 and DEMBOOSTA[1:0] bits.

The DC/DC A converter cannot be switched on while the CPRES1 pin remains inactive. If CPRES1 pin becomes inactive while the DC/DC A converter is operating an automatic shut down sequence of the DC/DC A converter is initiated by the electronics.

A write operation in VCARD1[1:0] (0x01, 0x02, 0x03) starts the DC/DC. When the output voltage remains within the voltage range specified by VCARD1[1:0], the VCARD\_OK1 bit is set.

After a deactivation sequence (card extraction, DC/DC output voltage out of range, SHUT-DOWNA bit =1...) the DC/DC A converter is automatically stopped.

It is mandatory to switch off the DC/DC A converter before entering in Power-down mode.

The DC/DC A Converter can work in two different modes which are selected by STEPREGA bit:

- Pump Mode (STEPREGA = 0): an external inductance of 10  $\mu$ H must be connected between pins LIA and VCC. VCC can be higher or lower than CVCC1.
- Regulator mode (STEPREGA = 1): no external inductance is required but VCC must be always higher than CVCC+0.3V.

The current drawn from power supply by the DC/DC A converter is controlled during the startup phase in order to avoid high transient current mainly in Pump Mode which could cause the power supply voltage to drop dramatically. This control is done by means of bits DEM-BOOSTA[1:0], which increases progressively the startup current level.

The DC/DCA sensitivity to any overflow current can be modified (20%) by using the ICCADJA bit (SC1\_CFG3 register).

#### Initialization Procedure for DC/DC A converter

The initialization procedure is described in flow chart:

- Select the CVCC1 level by means of bits VCARD1[1:0] in SC1\_CFG0 register,
- Set bits DEMBOOSTA[1:0] in SC1\_CFG4 register following the current level control wanted.
- Monitor VCARD\_OK1 bit in SC1\_STATUS register in order to know when the DC/DC A Converter is ready (CVCC1 voltage has reached the expected level)

While VCC1 remains higher than 3.6V and startup current lower than 30 mA (depending on the load type), the DC/DC A converter should be ready without having to increment DEM-BOOSTA[1:0] bits beyond [0:0] level. If at least one of the two conditions are not met (VCC < 3.6V or startup current > 30 mA), it will be necessary to increment the DEMBOOSTA[1:0] bits until the DC/DC converter is ready.

Increment of DEMBOOSTA[1:0] bits increases at the same time the current overflow level in the same proportion as the startup current. So once the DC/DC converter is ready it advised to decrement the DEMBOOSTA[1:0] bits to restore the overflow current to its normal or desired value.

#### **DC/DC B converter**

The DC/DC B converter is controlled by DCDCB register.

The DC/DC B converter can be switched on even if CPRES2 pin remains inactive.

A write operation in VDCB[1:0] (0x01, 0x02, 0x03) starts the DC/DC. When the output voltage remains within the voltage range specified by VDCB\_OK[1:0], the VDCB\_OK bit is set.

The DC/DC B Converter can work in two different modes which are selected by STEPREGB:

- Pump Mode (STEPREGB = 0): an external inductance of 10 μH must be connected between pins LIB and VCC. VCC can be higher or lower than selected voltage.
- Regulator mode (STEPREGB = 1): no external inductance is required but VCC must be always higher than selected voltage+0.3V.

The current drawn from power supply by the DC/DC B converter is controlled during the startup phase in order to avoid high transient current mainly in Pump Mode which could cause the power supply voltage to drop dramatically. This control is done by means of bits DEM-BOOSTB[1:0], which increases progressively the startup current level.

The DC/DCB sensitivity to any overflow current can be modified (20%) by using the ICCADJB bit (DC/DCB register).

#### Initialization Procedure for DC/DC B converter

The initialization procedure is described in flow chart:

- Select the DC/DC B level by means of bits VDCB[1:0] in DCDCB register,
- Set bits DEMBOOSTB[1:0] in INTERFACEB register following the current level control wanted.
- Monitor VDCB\_OK bit in DCDCB register in order to know when the DC/DC B Converter is ready

Figure 10. DC/DC B Converter Initialization Procedure

Increment of DEMBOOSTB[1:0] bits increases at the same time the current overflow level in the same proportion as the startup current. So once the DC/DC B converter is ready it advised to decrement the DEMBOOSTB[1:0] bits to restore the overflow current to its normal or desired value.

22 AT83C26

#### LDO initialization Procedure

When the DC/DC B voltage rises the selected voltage (VDCB\_OK=1), the card voltage selection on CVCC2, CVCC3, CVCC4 or CVCC5 starts the corresponding LDO.

The CVCC2 card voltage must be started in first (if needed). When the VCARD\_OK2 is set, the CVCC3,CVCC4, CVCC5 card voltage are started one after each other (if needed) with the same procedure.

The LDO2, LDO3, LDO4 and LDO5 share the DC/DCB output current, for example 75mA max when CVCCB is pregrammed to 5V. (see Table 62.)

The SC2\_FULL bit must be set to use SC2 full interface:

CIO3/CC42 is CC42 and CRST3/CC82 is CC82.

As the power supply of CIO3/CC42 and of CRST3/CC82 is CVCC3, when SC2\_FULL=1, CVCC3 = CVCC2. The SC3 interface is disable and LDO3 receives LDO2 command (VCARD3[1:0] = VCARD2[1:0]).

The LDOn output voltage must be at 0V before to program 1.8V/3V/5V.

# Activation Sequence Overview (n=1, 2, 3, 4, 5)

The activation sequence on SC1 is only available if a card is detected on CPRES1 (CARDIN1 bit = 1).

The activation sequence on SC2 is only available if a card is detected on CPRES2 (CARDIN2 bit = 1).

The activation sequence on SC3, SC4, SC5, is only available if DC/DC B is started (VDCB\_OK = 1).

The SCn interface starts the activation sequence after a TWI write command in VCARDn[1:0] bits to program the CVCCn voltage.

The SC3, SC4, SC5 interfaces (SIM/SAM interfaces) don't have card presence detector.

After the DC/DC start, the user application will check the ATR to detect if a SIM/SAM is present in the connector.

The automatic reset transition mode (ART=1) controls the CRST pin and check if the first start bit of the ATR respects ISO7816 timings.

All status bits of an interface (see bits in registers with "This bit is cleared by hardware when this register is read") must be cleared before to start an activation sequence.

#### Software Activation for SCn interfaces (n=1, 2, 3, 4, 5) with ARTn bit = 0

The activation sequence is controlled by software using TWI commands, depending on the cards to support. For ISO 7816 cards, the following sequence can be applied:

- 1. Card Voltage is set by software to the required value (VCARDn[1:0] bits). The TWI writing command in VCARDn[1:0] starts the DC/DC (or LDO).
- Wait of the end of the DC/DC (or LDO) init with a polling on VCARD\_OKn bit or wait for INT to go Low. When VCARD\_OKn bit is set (by hardware), CARDIOn bit should be set by software.
- 3. CKSTOPn, IODISn are programmed by software. CKSTOPn bit is reset to have the clock running. IODISn (see IO\_SELECT for SC2, SC3, SC4, SC5) is reset to enable the transparent mode on CIOn,CC4n, CC8n.
- 4. CRSTn pin is controlled by software using CARDRSTn bit.

<sup>24</sup> **AT83C26** 

Figure 14. Software activation without automatic control (ARTn bit = 0)

Note:

- It is assumed that initially VCARDn[1:0], CARDCKn, CARDIOn and CARDRSTn bits are cleared, CKSTOPn and IODISn are set (those bits are further explained in the registers description)
- The user should check the AT83C26 status and possibly resume the activation sequence if one TWI transfer is not acknowledged during the activation sequence.

#### Software activation for SCn (n=1, 2, 3, 4, 5) interfaces and ARTn bit = 1

The following sequence can be applied:

- 1. Card Voltage is set by software to the required value (VCARDn1:0] bits in SCn\_CFG0 register). This writing starts the DC/DC converter (or LDO).
- 2. Wait of the end of the DC/DC init (or LDO) with a polling on VCARD\_OKn bit or wait for INT to go Low. When VCARD\_OKn bit is set (by hardware), CARDIOn bit should be set by software.
- 3. CKSTOPn, IODISn are programmed by software. CKSTOPn bit is reset to have the clock running. IODISn is reset to enable the transparent mode on CIOn,CC4n, CC8n.
- 4. CARDRSTn bit is set by software.

#### Automatic Reset Transition description:

A 16-bit counter starts when CARDRSTn bit is set. It counts card clock cycles. The CRSTn signal is set when the counter reaches the TIMER\_MSB and TIMER\_LSB value which corresponds to the "tb" time (Figure 15). The counter is reseted when the CRSTn pin is released and it is stopped at the first start bit of the Answer To Request (ATR) on CIOn pin.

The CIOn pin is not checked during the first 200 clock cycles (ta, Figure 15). If the ATR arrives before the counter reaches TIMER\_MSB and TIMER\_LSB values, the activation sequence fails,

the CRSTn signal is not set and the CAPTURE\_MSB and CAPTURE\_LSB registers contain the value of the counter at the arrival of the ATR.

If the ATR arrives after the rising edge on CRSTn pin and before the card clock counter overflows (65535 clock cycles), the activation sequence completes. The CAPTURE\_MSB and CAPTURE\_LSB registers contain the value of the counter at the arrival of the ATR (tc time on Figure 15).

ISO 7816 constraints: ta = 200 card clock cycles

400 card clock cycles< = tb

400 card clock cycles< = tc < = 40000 card clock cycles

Timer[1-0] reset value is 400.

#### Warm reset (n=1, 2, 3, 4, 5)

The AT83C26 offers a simple and accurate way to control the CRSTn signal during a warm reset.

After an activation sequence (cold reset), a warm reset is started with a low level on CRST during a define delay (between 40000 and 45000 clock cycles for example).

The ARTn bit, the TIMER\_MSB and the TIMER\_LSB are used to control CRSTn.

The first step is to load the number of CCLK cycles with CRSTn=0 in TIMER registers.

The warm reset is started by setting ART bit (if ART bit is already set, reset ART before).

<sup>26</sup> AT83C26

The CRST signal will be equal to 0 during the number of clock cycles programmed in TIMER\_MSB and TIMER\_LSB. Then, the CRST signal will be at 1.

### **Deactivation Sequence Overview**

The deactivation sequence should follows the order defined in ISO7816-3 specification. The AT83C26 has two deactivation modes:

- Standard deactivation mode: This mode is used to stop exchange with smart card when the AT83C26 power supply is present. The DCCLK signal is used for deactivation sequence timings.
- Emergency deactivation mode: This mode is used when the AT83C26 power supply is took off.

#### Deactivation sequence on SCn interface (n=1, 2, 3, 4, 5)

The card automatic deactivation is triggered when one the following condition occurs:

- ICARDERR1 bit is set by hardware (SC1)
- VCARDERRn bit is set by hardware (or by software)
- INSERT1 is set and CARDIN1 is cleared (SC1)
- INSERT2 is set and CARDIN2 is cleared (SC2)
- SHUTDOWNA bit is set by software (SC1)
- SHUTDOWNB bit is set by software (SC2, SC3, SC4, SC5)

- Reset pin going low (SC1, SC2, SC3, SC4, SC5)
- Power Fail (VPFDP)

It is a self-timed sequence which cannot be interrupted when started (see Figure 17). Each step is separated by a delay based on Td equal to 8 periods of DCCLK, typically 2 to 2.4  $\mu$ s:

- 1. T0: CARDRSTn is cleared, SHUTDOWNA (for SC1) bit is set.
- 2. T0 + 5 x Td:CARDCKn is cleared, CKSTOPn, CARDIOn and IODIS are set.
- 3. T0 + 6 x Td: CARDIOn is cleared.
- 4. T0 + 7 x Td: VCARDn[1:0] = 00.

Figure 17. Deactivation Sequence

- Notes: 1. Setting ICARDERR1 by software does not trigger a deactivation on SC1. VCARDERRn can be used to deactivate the card by software.
  - If CCLKn=A2 or A2/2, deactivation follows fig13 with 2 timing modifications: t1=5.5\*Td and t2=0.5\*Td.
  - 3. Td is based on DCCLK clock.

#### Emergency deactivation sequence on SCn interface (n=1, 2, 3, 4, 5)

The card emergency automatic deactivation is triggered when one the following condition occurs:

- Software TWI Reset (SC1, SC2, SC3, SC4, SC5)
- Power fail on VCC (SC1, SC2, SC3, SC4, SC5)

If the power supply is disconnected, a standard deactivation is started when VCC = VPFDP. When VCC is equal to VPFDM, the emergency deactivation occurs and eventually ends the standard deactivation.

Figure 19. Emergency deactivation sequence

During an emergency deactivation, the signals fall according to the order described in Fig18.

# **Transparent mode**

#### Full transparent mode on SCn interfaces (n=1, 2)

If the micro controller outputs ISO 7816 signals, a transparent mode allows to connect, CCLK, CIO, CRST, CC4 and CC8 signals on outputs after an electrical level control. The AT83C26 level shifters adapt the card signals to the smart card voltage selection.

The CCLK micro controller signal can be connected to the A2/CK pins (see CKSn[2:0]).

CKSn[2:0] bits allow to select standard or transparent configuration for the CCLKn pin. A2/CK inputs always give the TWI address at reset.

If A2/CK input is tied to the host micro controller and its reset value is unknown, a general call on the TWI bus allows to reset all the AT83C26 devices and set its address after A2/CK input is fixed.

Figure 20. Transparent Mode Description

#### Full transparent mode on SCn interfaces (n= 3, 4, 5)

The transparent mode with A2/CK is also available for SC3, SC4 and SC5 interfaces without CC4 and CC8.

Figure 21. Transparent Mode Description

### Interrupts

The INT output is High by default. INT is driven Low by at least one of the following event:

- INSERT1 or INSERT2 bits set (card insertion/extraction or bit set by software)
- VCARD\_INTn (n=1,2,3,4,5) bits set (the DC/DC A or LDO2 to LDO5 output voltage has settled)
- VDCB\_INT bit set (the DC/DC B output voltage has settled)
- over-current detection on CVCC1
- VCARDERRn bit set (out of range voltage on CVCCn or bit set by software) (n=1,2,3,4,5)
- ATRERRn bit set (no ATR before the card clock counter overflows or bit set by software) (n=1,2,3,4,5)

30 **AT83C26** 

Several AT83C26 devices can share the same interrupt pin and the micro controller can identify the interrupt sources by polling the interrupt bits of the AT83C26 devices using TWI commands.

A TWI read command of the interrupt bit corresponding to the IT clears the bit. When all IT bits are cleared, the INT output becomes high.

The ITDIS register contains 4 bits to control SCn interrupts (n= 2,3,4,5). If ITDISn bit is set, the flags are set but the  $\overline{INT}$  pin isn't driven low if an interrupt event appears.

| Bit name   | Register name | $\frac{\text{Mask on}}{\text{INT pin}}$ | Remark   |
|------------|---------------|---|--|
| INSERT1    | SC1_CFG0      |   | Smart card inserted/extracted in SC1             |
| INSERT2    | SC2_CFG0      | ITDIS2                                  | Smart card inserted/extracted in SC2             |
| VCARD_INT1 | SC1_STATUS    |   | VCARD_OK1 is set                                 |
| VCARD_INT2 | SC2_CFG0      | ITDIS2                                  | VCARD_OK2 is set                                 |
| VCARD_INT3 | SC3_CFG0      | ITDIS3                                  | VCARD_OK3 is set                                 |
| VCARD_INT4 | SC4_CFG0      | ITDIS4                                  | VCARD_OK4 is set                                 |
| VCARD_INT5 | SC5_CFG0      | ITDIS5                                  | VCARD_OK5 is set                                 |
| VDCB_INT   | DCDCB         |   | VDCB_OK is set                                   |
| ICARDERR1  | SC1_CFG0      |   | Over current on DCDCA.                           |
| VCARDERR1  | SC1_CFG0      |   | Ouput voltage out of range on DCDCA              |

Table 4. Interrupt bits description

After the reading and the clear of the interrupt bits, several bits are used to control the status.

| Table 5. | Status | bits | description |
|----------|--------|------|-------------|
|----------|--------|------|-------------|

| Bit name  | Register name | Remark   |
|-----------|---------------|--|
| CARDIN1   | SC1_STATUS    | Smart card presence in SC1                       |
| CARDIN2   | SC1_STATUS    | Smart card presence in SC2                       |
| VCARD_OK1 | SC1_STATUS    | CVCC1 voltage in range programmed in VCARD1[1:0] |
| VCARD_OK2 | SC2_CFG0      | CVCC2 voltage in range programmed in VCARD2[1:0] |
| VCARD_OK3 | SC3_CFG0      | CVCC3 voltage in range programmed in VCARD3[1:0] |
| VCARD_OK4 | SC4_CFG0      | CVCC4 voltage in range programmed in VCARD4[1:0] |
| VCARD_OK5 | SC5_CFG0      | CVCC5 voltage in range programmed in VCARD5[1:0] |
| VDCB_OK   | DCDCB         | CVCCB voltage in range programmed in VDCB[1:0]   |

The status for the ICARDERR1 and VCARDERRn (n=1 to 5) bits is controlled with VCARD\_OKn bits.

The status for the ATRERRn (n= 1 to 5) is controlled by reading of values in CAPTURE\_MSB and CAPTURE\_LSB.

#### Slew rate control

The AT83C26 proposed a slew rate control on CIOn and CCLKn pins (n=1, 2, 3, 4, 5). The control operates on rising and falling edges of CCLKn and only on rising edge of CIOn.

Four modes are available:

- Automatic mode: The slew rate depends on VCARDn[1:0] value. The slew rate value is
  optimized according to CVCCn.
- Mode 1, 2, 3 (1.8V, 3V, 5V): The user can forced the slew rate if needed. For example if CVCCn = 5V, the user can program 1.8V or 3V to speed up the slew rate in case of long wire connection between AT83C26 and smart cards.

#### Power down mode

SHUTDOWNA bit and SHUTDOWNB bit must be set to activate power down mode on DCDCA and DCDCB converters.

If SHUTDOWNA = SHUTDOWNB = 1, the AT83C26 internal regulator also enters in power down mode. The consumption is then about  $30\mu$ A.

To exit from power down mode, TWI commands are needed to clear SHUTDOWNA and SHUTDOWNB.

32 **AT83C26** 

# Write Commands

The write commands are:

- General Call Reset:
   A general call followed by the value 06h has the same effect as a Reset command.
- 2. Reset:

Initialize all the logic and the TWI interface as after a power-up or power-fail reset. If the interface is activated, an emergency de-activation sequence is also performed. This is a one-byte command.

3. Write SC1\_CFG0, SC1\_CFG1, SC1\_CFG2, SC1\_CFG3, SC1\_CFG4:

Configure the device according to the last six bits in the SC1\_CFG0 register and to the following four bytes in SC1\_CFG1, SC1\_CFG2, SC1\_CFG3 then SC1\_CFG4 registers. This is a five bytes command.

Figure 22. Command byte format for Write SC1\_CFG0 command

| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|----|----|----|----|----|----|----|----|
| 1  | 0  | x  | x  | x  | x  | x  | x  |

SC1\_CFG0 on 6 Bits

4. Write TIMER\_MSB, TIMER\_LSB:

Program the 16-bit automatic reset transition timer with the following two bytes. This is a three bytes command.

5. Write SC1\_INTERFACE:

Program the interface byte. This is a one-byte command. The MSB of the command byte is fixed at 0.

- Write common config smart cards: IO\_SELECT, INTERFACE\_B, ITDIS: Configuration of parameters for smart card interfaces.
- 7. Write SC2 interface: SC2\_CFG0, SC2\_CFG1, SC2\_CFG2 Configuration of smart card interface 2.
- 8. Write SC3 interface: SC3\_CFG0, SC3\_CFG2 Configuration of SIM/SAM interface 3.
- 9. Write SC4 interface: SC4\_CFG0, SC4\_CFG2 Configuration of SIM/SAM interface 4.

- 10. Write SC5 interface: SC5\_CFG0, SC5\_CFG2 Configuration of SIM/SAM interface 5.
- 11. Write DCDCB config: DCDCB, LDO Configuration of DCDCB converter.
- 12. Write SLEW\_CTRL config: SLEW\_CTRL\_1, SLEW\_CTRL\_2, SLEW\_CTRL\_3 Configuration of slew rate for CCLKn and CIOn (n = 1, 2, 3, 4, 5).

Table 6. Write Commands Description

# **Read Command**

After a write command, even with a length of 0 byte, the next read operation is performed on the corresponding byte. The write command sets the "read pointer".

After the reset, the "read pointer" is on SC1 registers

FFh is completing the transfer if the micro controller attempts to read beyond the last byte. Flags are only reseted after the corresponding byte read has been acknowledged by the master.

Figure 23. Read command byte

## Absolute Maximum Ratings

| Ambient Temperature Under Bias: 40°C to 85°C            |
|---|
| Storage Temperature:65°C to +150°C                      |
| Voltage on VCC: $V_{SS}\mbox{-}0.5V$ to +6.0V           |
| Voltage on SCIB pins (***): CVSS -0.5V to CVCC + 0.5V   |
| Voltage on host interface pins:VSS -0.5V to EVCC + 0.5V |
| Voltage on other pins: VSS -0.5V to VCC + 0.5V          |
| Max Power Dissipation:                                  |
| Thermal resistor of QFN package (**)24 °C/W             |
| Thermal resistor of VQFP package67 °C/W                 |

\*NOTICE: Stresses at or above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions may affect device reliability. Power Dissipation value is based on the maximum allowable die temperature and the thermal resistance of the package.

(\*\*) Exposed die attached pad must be soldered to ground Thermal resistor is measured on multi-layer PCB with 0 m/s air flow.

(\*\*\*) including shortages between any groups of smart card pins.

AC/DC ParametersEVCC connected to host power supply: from 2.5V to 5.5V. $T_A = -40^{\circ}C$  to  $+85^{\circ}C$ ;  $V_{SS} = 0V$ ;  $V_{CC} = 3V$  to 5.5V.CLASS A (5V) for smart card 1, 2, 3, 4, 5 supplied with CVCC (+/- 8%)CLASS B (3V) for smart card 1, 2, 3, 4, 5 supplied with CVCC (+/- 8%)CLASS C (1.8V) for smart card 1, 2, 3, 4, 5 supplied with CVCC (+/- 8%)
