

MIC3291

1.2MHz PWM White LED Driver with Internal Schottky Diode and Single-Wire Linear Brightness Control

General Description

The MIC3291 is a PWM switching boost regulator that is optimized for constant current white LED (WLED) driver applications. The MIC3291 features an internal Schottky diode, allowing an efficient DC/DC solution that requires only four external components.

The MIC3291 allows for a single-wire simple digital interface to control the dimming over 16 steps with a linear scale. The preprogramming feature allows the user to select any one of the 16 WLED current levels as the start up brightness level.

The feedback voltage of the MIC3291 is only 250mV, allowing high efficiency while retaining excellent accuracy for the WLED current.

The MIC3291 implements a constant frequency 1.2MHz PWM control scheme. The high frequency PWM operation saves board space by reducing external component sizes. The 1.2MHz PWM scheme also reduces switching noise and ripple to the input power source.

The 2.5V to 6.5V input voltage range of the MIC3291 allows direct operation from single cell Li-Ion as well as 3 to 4 cell NiCad/NiMH/Alkaline batteries. Battery life is preserved with a low 1 μ A shutdown current.

The MIC3291 is available in a low profile Thin SOT23 6-pin and 2mm \times 2mm MLF[®] 8-pin packages with a junction temperature range of -40°C to $+125^{\circ}\text{C}$.

Data sheets and support documentation can be found on Micrel's web site at: www.micrel.com.

Features

- Single wire combines 16 level linear brightness and shutdown control
- 18V / 25V OVP options supports up to four and six WLEDs
- Startup in any one of 16 brightness levels
- Internal Schottky diode
- 2.5V to 6.5V input voltage
- 1.2MHz PWM operation
- Over 500mA switch current
- 250mV reference voltage
- $\pm 5\%$ LED current accuracy
- $<1\mu\text{A}$ shutdown current
- UVLO and over-temperature protection
- Thin SOT23-6L package option
- 2mm \times 2mm leadless MLF[®] package option
- -40°C to $+125^{\circ}\text{C}$ junction temperature range

Applications

- Mobile handsets
- LCD handset backlighting
- Digital cameras
- Portable media players/MP3 players
- Portable applications

Typical Application

White LED Driver with OVP and Digital Control

T_J	Over-Temperature Threshold Shutdown			150		$^\circ\text{C}$

Notes:

1. Absolute maximum ratings indicate limits beyond which damage to the component may occur. Electrical specifications do not apply when operating the device outside of its operating ratings. The maximum allowable power dissipation is a function of the maximum junction temperature, $T_{J(\text{Max})}$, the junction-to-ambient thermal resistance, θ_{JA} , and the ambient temperature, T_A . The maximum allowable power dissipation will result in excessive die temperature, and the regulator will go into thermal shutdown.
2. IC devices are inherently ESD sensitive. Handling precautions required. Human body model, 1.5k Ω in series with 100pF.
3. This device is not guaranteed to operate beyond its specified operating rating.
4. Specification for packaged product only.

MIC3291 Block Diagram

Functional Description

The MIC3291 is a constant frequency, PWM current mode boost LED driver. It is composed of an oscillator, slope compensation ramp generator, current amplifier, gm error amplifier, PWM generator, bipolar output transistor, digital interface with D/A converter and Schottky rectifier diode. It features true single-wire linear digital control that may be used to vary the brightness of the output LEDs. The oscillator generates a 1.2MHz clock which triggers the PWM generator that turns on the output transistor and resets the slope compensation ramp generator. The current amplifier is used to measure the switch current by amplifying the voltage signal from the internal sense resistor. The output of the current amplifier is summed with the output of the slope compensation ramp generator. This summed current loop signal is fed to one of the inputs of the PWM generator.

MIC3291 Block Diagram

The gm error amplifier measures the LED current through the external sense resistor and amplifies the error between the detected signal and the reference voltage indicated by the digital interface. The output of the gm error amplifier provides the voltage loop signal that is fed to the other input of the PWM generator. When the current loop signal exceeds the voltage loop signal, the PWM generator turns off the bipolar output transistor. The next clock period initiates the next switching cycle, maintaining the constant frequency current mode PWM control. The LED current level at maximum brightness is set by the feedback resistor:

$$I_{LED} = \frac{250mV}{R_{LED}}$$

MIC3291 Digital Interface

The MIC3291 incorporates an easy to use single-wire, serial programming interface allowing users to set LED brightness to one of sixteen levels spaced in a linear manner. In contrast to other solutions requiring a PWM drive signal to maintain LED brightness, the MIC3291 is "set and forget", relieving the controlling processor of the constant burden of supplying a drive signal. Additionally, brightness levels can be preset so that LEDs can be turned on at a particular brightness level.

Brightness Level	FB Voltage (mV)

0	25

Table 1. Brightness Level vs. Ideal FB Voltage

Startup

Presuming no presetting brightness command is issued (discussed in a later section), the MIC3291 will startup in its default state approximately 140µs (t_{START_UP}) after a logic level high has been applied and maintained at the DC pin. In the default state the LED drive current is at the maximum brightness level of 15 and brightness counter is set to count down mode. Any falling edges during the t_{PROG_SETUP} period will cause the initial brightness level of the LEDs to be below the maximum brightness level. This is discussed in more detail in the *Presetting Brightness* section.

Figure 2. Typical Startup Timing

Shutdown

Whenever a logic level LOW is applied to the DC input pin for a period greater than or equal to $t_{SHUTDOWN}$ (1260 μ s), the MIC3291 will be in power saving shutdown mode.

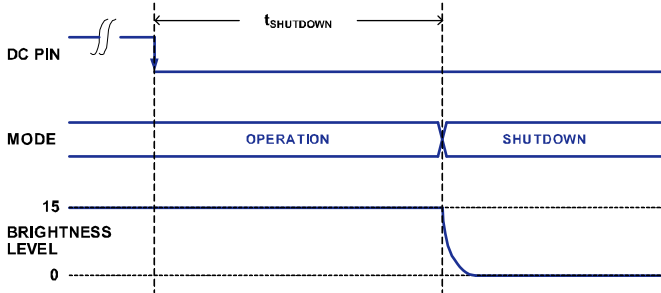

Figure 3. Shutdown Timing

Once the device is shutdown, the boost supply is disabled and the LEDs are turned off. Brightness level information stored in the MIC3291 prior to shutdown will be lost.

Programming Pulse Counter Modes

At power up the MIC3291 defaults to count down mode. In count down mode, the brightness level is decreased one level by applying two programming pulses, as shown in Figure 6. The counting mode can be changed to count up mode by pulling the DC pin LOW for a period equal to t_{MODE_UP} (100 μ s to 160 μ s). The device will remain in count up mode until its state is changed to count down mode or by disabling the MIC3291.

Figure 4. Mode Change to Count up

To change the state back to count down mode, pull the DC pin LOW for a period equal to t_{MODE_DOWN} (420 μ s to 500 μ s). Now the internal circuitry will remain in count down mode until changed to count up mode as described previously.

Figure 5. Mode Change to Count Down

Programming the Brightness Level

MIC3291 is designed to start driving the output LEDs (t_{START_UP}) in 140 μ s at the maximum brightness level of 15. After startup, the internal control logic is ready to decrease the LED brightness upon receiving programming pulses (negative edges applied to DC pin). Since MIC3291 starts in count down mode, the brightness level is decreased one level by applying two programming pulses, as shown in Figure 6. Each programming pulse has a high (t_{PROG_HIGH}) and a low (t_{PROG_LOW}) pulse width that must be between 1 μ s to 32 μ s. Note that n+1 number of pulses are needed to decrease brightness by n level(s) since the first clock pulse is ignored. Ignoring the first clock pulse is necessary so mode change (t_{MODE_UP} , t_{MODE_DOWN}) pulses do not result in adjustments to the brightness level. The MIC3291 internal circuit can be changed from count down mode to count up mode and vice versa. The user may elect to send a mode change as shown in Figure 4 to set the MIC3291 to step up the brightness level with subsequent programming pulses. For proper operation, ensure the DC pin has remained HIGH for at least t_{DELAY} (140 μ s) before issuing a mode change command.

Figure 6. Brightness Programming Pulses

Multiple brightness levels can be changed together with multiple programming pulses, as shown in Figure 7. When issuing multiple brightness level adjustment commands to the DC pin, ensure both t_{PROG_LOW} and t_{PROG_HIGH} are within 1 μ s and 32 μ s.

To maintain operation at the current brightness level simply maintain a logic level high signal at the DC pin.

Figure 7. Decreasing Brightness Several Levels

As mentioned, MIC3291 can be programmed to set LED drive current to produce one of 16 distinct brightness levels. The internal logic keeps track of the brightness level with an up/down counter circuit. The *Counter Rollover* section explains how the brightness counter functions with continued programming edges.

Counter Rollover

The MIC3291 internal up/down counter contains registers from 0 to 15. When the brightness level is at 0 and a programming pulse forces the brightness to step down, then the counter will rollover to Level 15. This is illustrated in Figure 8.

Figure 8. Down Counter Rollover

Similarly, when the counter mode is set to count up and a programming pulse forces the brightness level to step up from level 15, then the counter will rollover to level 0 as illustrated in Figure 9.

Figure 9. Up Counter Rollover

One Step Brightness Changes

For applications where a keypad button press is to be translated into a brightness level change, the following method of decreasing the brightness level may be useful. This “one step” brightness change procedure relieves the user from keeping track of the MIC3291’s up/down counter mode. It combines a counter mode change with a programming pulse, therefore a one step decrease in brightness is assured no matter what the previous up/down counter mode was.

Figure 10. One step Brightness Decrease

This method is quite simple and the only requirement is that the first DC LOW period be equal to the t_{MODE_DOWN} (420µs to 500µs) and immediately followed by a falling edge within t_{PROG_HIGH} (1µs to 32µs) as shown in Figure 10 for one step brightness decrease. Similarly a one step increase can be assured by first generating a DC down pulse whose period is equal to the t_{MODE_UP} (100µs to 160µs) and immediately followed by a falling edge within t_{PROG_HIGH} (1µs to 32µs). Figure 11 illustrates the proper timing for execution of a one step brightness increase.

Figure 11. One step Brightness Increase

Presetting Brightness

The brightness level can be preset before the MIC3291 begins to drive the LEDs by sending a series of programming edges via the DC pin during the t_{START_UP} (140 μ s) period and between 35 μ s to 50 μ s after the DC pin is first pulled HIGH. The 15 μ s timeframe between 35 μ s and 50 μ s is the t_{PROG_SETUP} period. The MIC3291 does not drive current into the load until DC pin is kept HIGH for t_{START_UP} (140 μ s) after presetting has concluded in order to grant the user sufficient time to preset LED brightness. The first presetting pulse edge must occur somewhere between the timeframe of 35 μ s to 50 μ s after DC pin is first pulled HIGH otherwise the MIC3291 may continue to start at the full (default) brightness level.

Figure 12 shows the correct presetting sequence to set the MIC3291 brightness to Level 6 prior to startup. The sequence is initiated by driving the DC pin LOW for a period exceeding $t_{SHUTDOWN}$ (1260 μ s) to insure that the part has entered the power saving shutdown state erasing all brightness level state and mode setting. Then the DC pin is driven HIGH and the first presetting pulse edge is entered within the t_{PROG_SETUP} window. Notice that when using the presetting feature the first programming pulse is not ignored. This is because the counter's default mode is count down and a mode change cannot be performed in the presetting mode. (Note that the same timing requirements of standard brightness programming also apply during presetting brightness.)
